Abstract—A method which ensures uniqueness of the polyhedral partition of the parameter space for convex multiparametric quadratic programs (mp-QP) is presented. When the mp-QP has non-unique solutions, the norm of the solution vector is minimized and a unique affine optimizer function is identified for each region. It is proven, that under certain assumptions on the problem data, a globally continuous piecewise affine optimizer function is selected.

Index Terms—Multiparametric programming, constrained optimal control, quadratic programming, normal cone optimality condition, explicit model predictive control.

I. INTRODUCTION

Several efficient algorithms for solving multiparametric quadratic programs (mp-QP) have been developed recently [1], [2], [3]. The growing interest in multiparametric problems is due to the fact that explicit solutions to model predictive control problems can be obtained by solving multiparametric programs [1], [4].

Substantial work has been done on the continuity properties of the value function and optimal solution set for multiparametric problems [5], [6], [7], [8], [9], [10]. Continuity of the optimal set mapping is closely related to the stability of the optimization problem and the stability of quadratic programs is studied in [11] and [12]. Continuity and stability results for multiparametric programs are often derived from set theory presented in [13], [14] and [15].

The algorithm presented by Bemporad et al. [1] obtains solutions to strictly convex mp-QPs, however, with some modifications, it can also be used for convex problems [2]. Borrelli et al. [16] proposed a geometric algorithm for multiparametric linear programs (mp-LP) that explores the parameter space in the same manner as in [1]. Common to the algorithms for convex mp-QP, including the geometric algorithm for mp-LP, is that the optimizer function may be discontinuous even if the optimal solution set is a continuous point to set map and therefore admits a continuous selection [17]. Moreover, the polyhedral partition of the parameter space is generally non-unique and may consist of polyhedra with intersecting interiors. A method which ensures continuity of a particular optimizer selection for mp-LPs, without parameters in the objective function, is presented in [18].

We point out that using the normal cone optimality condition to construct parametric regions of optimality for strictly convex mp-QPs [19] results in a unique polyhedral partition. For convex mp-QP a unique, non-intersecting partition is obtained by always choosing the solution with the least Euclidian norm. If the mp-QP has non-unique solutions, a strictly convex mp-QP is formulated such that the norm of the solution vector is minimized subject to the optimality conditions of the original problem.

A unique, non-intersecting polyhedral partition of the parameter space ensures that the polyhedra in the piecewise affine mapping are independent of the algorithm used to explore the parameter space.

If the optimal set mapping for the convex mp-QP is continuous, the minimum norm selection will be a globally continuous mapping from parameter to solution space.

Convex mp-QPs is a problem that arises in explicit soft-constrained model predictive control [20], as a sub-problem in mp-NLP algorithms [21], and for explicit model predictive control with a linear cost function [4]. Discontinuities of the optimizer function may lead to chattering in an optimal control approach, and hence, a method which yields a continuous optimizer function is desirable.

II. PRELIMINARIES

A. Problem setup

The standard formulation of an mp-QP is as follows

$$z^*(\theta) \triangleq \min_{x \in \mathbb{R}^n} \{f(x, \theta) \mid Ax \leq b + S\theta\}, \quad (1)$$

where $f(x, \theta) \triangleq \frac{1}{2}x^T Hx + \theta^T F^T x + c^T x$, $\theta \in \mathbb{R}^s$ is a parameter of the optimization problem, and the vector $x \in \mathbb{R}^n$ is to be optimized for all values of $\theta \in \Theta$, where $\Theta \subseteq \mathbb{R}^s$ is some polyhedral set. Moreover $H = H^T \in \mathbb{R}^{n \times n}$, $F \in \mathbb{R}^{n \times s}$, $A \in \mathbb{R}^{q \times n}$, $b \in \mathbb{R}^{q \times 1}$ and $S \in \mathbb{R}^{q \times s}$ are matrices. If in addition, $H \geq 0$ or $H > 0$, the mp-QP is convex or strictly convex, respectively. If $H = 0$, then (1) is referred to as a multiparametric linear program (mp-LP), which is a subclass of the problem addressed in this paper.

Recall that the set of affine combinations of points in a set $S \subset \mathbb{R}^n$ is called the *affine hull* of S . The *dimension* of a set $S \subset \mathbb{R}^n$, denoted $\dim(S)$; is the dimension of the affine hull of S . If the dimension of S is n , then S is said to be full-dimensional.

*Corresponding author.

Let the set of parameters for which the minimum in (1) exists be denoted Θ^* and let $X^*(\theta)$ be the set of optimizers to (1) for a given $\theta \in \Theta^*$. Without loss of generality it is assumed that Θ^* is full-dimensional, see [16] for details. The feasible set of (1) for a given $\theta \in \Theta$ is given by $\mathcal{P}(\theta) \triangleq \{x \in \mathbb{R}^n \mid Ax \leq b + S\theta\}$. We seek the value function $z^* : \Theta^* \mapsto \mathbb{R}$ and an optimizer function $x^* : \Theta^* \mapsto \mathbb{R}^n$, which is continuous if the problem admits a continuous selection.

We will use the following notation: if A is a matrix, then A_i denotes the i^{th} row of A and $A_{\mathcal{J}}$ denotes the submatrix consisting of the rows of A corresponding to the index set $\mathcal{J}$.

The following definitions are taken from [2] [16].

Definition 1 (Active set): Let x be a feasible solution to (1) for a given θ . We define the *active constraints* as the set of constraints which fulfill $A_i x - b_i - S_i \theta = 0$, and *inactive constraints* as the set which fulfills $A_i x - b_i - S_i \theta < 0$. The *active set* $\mathcal{A}(x, \theta)$ is the set of indices of the active constraints, that is,

$$\mathcal{A}(x, \theta) \triangleq \{i \in \{1, \dots, q\} \mid A_i x - b_i - S_i \theta = 0\}.$$

Moreover, let $\mathcal{N}(x, \theta)$ denote the set of inactive constraints, that is, $\mathcal{N}(x, \theta) \triangleq \{1, \dots, q\} \setminus \mathcal{A}(x, \theta)$.

Definition 2 (Optimal active set): Let θ be given. Let the *optimal active set* $\mathcal{A}^*(\theta)$ be the set of constraints which are active for all $x \in X^*(\theta)$, that is

$$\begin{aligned} \mathcal{A}^*(\theta) &\triangleq \{i \mid i \in \mathcal{A}(x, \theta), \forall x \in X^*(\theta)\} \\ &= \bigcap_{x \in X^*(\theta)} \mathcal{A}(x, \theta). \end{aligned}$$

Let $\mathcal{N}^*(\theta) \triangleq \{1, \dots, q\} \setminus \mathcal{A}^*(\theta)$.

Definition 3 (LICQ): For an active set $\mathcal{A}$, we say that the *linear independence constraint qualification (LICQ)* holds if the set of active constraint gradients are linearly independent, i.e., $A_{\mathcal{A}}$ has full row rank.

Definition 4 (Critical region): Given an optimal active set $\mathcal{A}^*$ we define the *critical region* as the set of parameters for which the optimal active set remains unchanged, that is,

$$\Theta_{\mathcal{A}^*} \triangleq \{\theta \in \Theta \mid \mathcal{A}^*(\theta) = \mathcal{A}^*\}. \quad (2)$$

It should be noted that critical regions are convex and that their closures are polyhedral. Since the optimal active set is unique for all $\theta \in \Theta^*$, critical regions cannot intersect, however, the intersection of their closures may be non-empty. Since Θ^* is assumed to be full-dimensional and the number of optimal active sets is finite, there exists a finite number of full-dimensional critical regions such that the union of their closures is equal to Θ^* .

Theorem 1 (Solutions to an mp-QP): A solution to a convex mp-QP can be represented as a piecewise affine mapping

$$x^*(\theta) = x_{\mathcal{A}}^*(\theta) \text{ if } \theta \in R_{\mathcal{A}}, \quad (3)$$

where $R_{\mathcal{A}} \subseteq \Theta^*$ are closed, full-dimensional, and convex polyhedral sets such that

$$\bigcup_{\mathcal{A} \in \mathcal{I}} R_{\mathcal{A}} = \Theta^*, \quad (4)$$

and $\mathcal{I}$ is a subset of all possible active sets $\{\mathcal{A}(x^*(\theta), \theta) \mid \theta \in \Theta^*\}$.

Proof: See [1] and [2]. ■

The polyhedra $R_{\mathcal{A}}$ will be defined as described below, and it should be noted that our definitions differ slightly from those in [1] and [2]. Given a $\theta \in \Theta^*$ and the associated optimal active set $\mathcal{A}^*$ such that $\Theta_{\mathcal{A}^*}$ is full-dimensional. If $X^*(\theta)$ is a singleton for all $\theta \in \text{cl}(\Theta_{\mathcal{A}^*})$, then $R_{\mathcal{A}^*} \triangleq \text{cl}(\Theta_{\mathcal{A}^*})$. If $X^*(\theta)$ is not a singleton for all $\theta \in \text{cl}(\Theta_{\mathcal{A}^*})$, then $\Theta_{\mathcal{A}^*}$ is divided into a finite set of full-dimensional polyhedra, whose union is equal to $\text{cl}(\Theta_{\mathcal{A}^*})$, where each polyhedron is associated with only one affine optimizer function. We will refer to these polyhedra as *sub-regions*. The optimal solution function $x^*(\theta)$ is single valued, since if a given θ is in more than one $R_{\mathcal{A}}$, $x_{\mathcal{A}}^*(\theta)$ is chosen according to some predetermined ordering of the sets in $\mathcal{I}$.

Definition 5 (Non-intersecting solution): We say that a solution to an mp-QP is *non-intersecting* if every pair $(\mathcal{A}_i, \mathcal{A}_j) \in \mathcal{I} \times \mathcal{I}$ satisfies

$$\dim(R_{\mathcal{A}_i} \cap R_{\mathcal{A}_j}) \leq s - 1, i \neq j.$$

If a solution satisfies Definition 5, then a given θ may only be in more than one $R_{\mathcal{A}}$ for lower dimensional subsets of Θ^* . Note that *closure of a full-dimensional critical region* is abbreviated to *critical region* from this point on.

B. Normal cone optimality condition

Recall that a set C is called a *cone* if for every $x \in C$ and scalar $\xi \geq 0$, we have $\xi x \in C$. Moreover, a cone represented by the intersection of a finite number of closed half-spaces is called an $\mathcal{H}$ -*cone*, and a cone represented by a finite number of rays is called a $\mathcal{V}$ -*cone*. If A is a matrix, then $\text{cone}(A)$ denotes the set of all nonnegative combinations of the column-vectors of A .

Consider the following problem

$$\begin{aligned} J^* &\triangleq \min_{x \in \mathbb{R}^n} \{f(x) \mid x \in \Omega\}, \\ \Omega &\triangleq \{x \in \mathbb{R}^n \mid g_i(x) = 0, i \in \mathcal{E}; g_j(x) \leq 0, j \in \mathcal{I}\}, \end{aligned}$$

where $\mathcal{E}$ and $\mathcal{I}$ are finite sets of indices, and f , g_i and g_j are smooth, real-valued functions on a subset of $\mathbb{R}^n$. The following definitions are taken from [22].

Definition 6 (Tangent Vector): A vector $w \in \mathbb{R}^n$ is tangent to Ω at x if for all vector sequences $\{x_i\}$ with $x_i \rightarrow x$ and $x_i \in \Omega$, and all positive scalar sequences $t_i \downarrow 0$, there is a sequence $w_i \rightarrow w$ such that $x_i + t_i w_i \in \Omega$ for all i .

Definition 7 (Tangent Cone): The tangent cone $T_{\Omega}(x)$ is the collection of all tangent vectors to Ω at x .

Definition 8 (Normal Cone): The normal cone to Ω at x , $N_{\Omega}(x)$, is the orthogonal complement of the tangent cone, that is

$$N_{\Omega}(x) = \{v \mid v^T w \leq 0, \forall w \in T_{\Omega}(x)\}. \quad (5)$$

Theorem 2 (First order necessary optimality condition): If x^* is a local minimizer of f in Ω , then

$$-\nabla_x f(x^*) \in N_{\Omega}(x^*). \quad (6)$$

Proof: See [22]. ■

If $f(x)$ and Ω are convex, then x^* is a global minimum and (6) is also sufficient.

Given the polyhedron $\Phi = \{x | Ax \leq b\}$. Let x_0 be a point on the boundary of Φ . Let $\mathcal{A}_0$ be the set of inequalities which are active at x_0 , hence $A_i x_0 = b_i$ for $i \in \mathcal{A}_0$, and $A_i x_0 < b_i$ for $i \notin \mathcal{A}_0$. Note that for a polyhedron the tangent cone $T_\Phi(x_0)$ at x_0 , is equal to the set of feasible directions at x_0 [23], i.e.

$$T_\Phi(x_0) = \{d | A_{\mathcal{A}_0} d \leq 0\}. \quad (7)$$

The normal cone at x_0 is defined as

$$N_\Phi(x_0) = \text{cone}(A_{\mathcal{A}_0}^T), \quad (8)$$

i.e. a $\mathcal{V}$ -cone with the rows of $A_{\mathcal{A}_0}$ defining the rays and a single vertex at the origin. Let the matrix L define the corresponding $\mathcal{H}$ -cone, that is

$$N_\Phi(x_0) = \{y | Ly \leq 0\}. \quad (9)$$

Note that any normal cone can also be associated with an active set, i.e. $N_\Phi(\mathcal{A}) = \{y | L_{\mathcal{A}} y \leq 0\}$. The optimality condition (6) becomes

$$L \nabla_x f(x_0) \geq 0. \quad (10)$$

III. STRICTLY CONVEX MP-QP

If $H > 0$ in (1), the problem can be reformulated such that only a quadratic term remains in the objective function [1]. Without loss of generality we use the following formulation for strictly convex mp-QP:

$$z^*(\theta) \triangleq \min_{x \in \mathbb{R}^n} \left\{ \frac{1}{2} x^T H x \mid Ax \leq b + S\theta \right\}. \quad (11)$$

In this section it is pointed out that constructing the regions in the solution as proposed in [19] yields a unique set of polyhedra for strictly convex mp-QP. Let $\mathcal{A}^*(\theta_0)$ be an optimal active set for (11). The optimizer function associated with $\mathcal{A}^*(\theta_0)$ is unique and represented as

$$x_{\mathcal{A}^*}^*(\theta) = K\theta + k, \quad (12)$$

where $K \in \mathbb{R}^{n \times p}$ and $k \in \mathbb{R}^n$ [1].

When it is clear from the context, the argument θ (or θ_0) will be omitted when referring to an optimal active or inactive set.

Theorem 3 (Critical region): The optimizer function $x_{\mathcal{A}^*}^*(\theta)$ associated with optimal active set $\mathcal{A}^*(\theta_0)$ is optimal in the polyhedron defined by

$$R_{\mathcal{A}^*} = \left\{ \theta \in \Theta \mid \begin{array}{l} A_{\mathcal{N}^*} x_{\mathcal{A}^*}^*(\theta) \leq S_{\mathcal{N}^*} \theta + b_{\mathcal{N}^*} \\ L_{\mathcal{A}^*} H x_{\mathcal{A}^*}^*(\theta) \geq 0 \end{array} \right\}, \quad (13)$$

where $L_{\mathcal{A}^*}$ is the normal cone defined by the optimal active set $\mathcal{A}^*(\theta_0)$.

Proof: See [19]. ■

Lemma 1 (Uniqueness of the solution): The solution to a strictly convex mp-QP obtained by defining sub-regions as in (13), is unique and satisfies Definition 5.

Proof: Uniqueness of the solution follows directly from uniqueness of $\mathcal{A}^*(\theta)$, $x_{\mathcal{A}^*}^*(\theta)$, and the normal cone $N_{\mathcal{P}(\theta)}$ for all $\theta \in \Theta^*$. Since $X^*(\theta)$ is a singleton for

all values of $\theta \in \Theta^*$, all $R_{\mathcal{A}^*}$ s in the solution are closures of critical regions. Since critical regions does not intersect, the property in Definition 5 is satisfied. ■

IV. CONVEX MP-QP

Consider problem (1). In the rest of the paper H is only restricted to be positive semidefinite and symmetric (this includes $H = 0$), and consequently, the optimizer for a given θ may be non-unique. We present a method which selects the optimizer function with minimum Euclidian norm. As in [18], the norm of the solution vector will be minimized subject to optimality conditions of the original problem and it is proven that the resulting solution is unique and non-intersecting.

A. Cone condition for convex QP

The cone condition was defined for a general class of optimization problems in section II-B. We state the optimality condition explicitly for (1);

$$L_{\mathcal{A}} (Hx + F\theta + c) \geq 0, \quad (14)$$

where $L_{\mathcal{A}}$ is the normal cone matrix corresponding to the active set $\mathcal{A}(x^*(\theta_0), \theta_0)$.

Proposition 1: Consider problem (1). Let $\theta = \theta_0$ and $\mathcal{A}^*(\theta_0)$ be the optimal active set and denote $\mathcal{P}(\theta_0)$ by $\mathcal{P}_0$. For any optimal solution $x^*(\theta_0)$ we have

$$-(Hx^*(\theta_0) + F\theta_0 + c) \in N_{\mathcal{P}_0}(\mathcal{A}^*(\theta_0)). \quad (15)$$

Proof: For $\mathcal{A}(x^*(\theta_0), \theta_0) = \mathcal{A}^*(\theta_0)$ this is the normal cone condition for optimality. We must show that (15) holds when $\mathcal{A}(x^*(\theta_0), \theta_0) \supset \mathcal{A}^*(\theta_0)$. Consider an optimal solution $\bar{x}^*(\theta_0)$ for which $\mathcal{A}(\bar{x}^*(\theta_0), \theta_0) = \mathcal{A}^*(\theta_0)$. Let $\tilde{x}^*(\theta_0)$ be optimal such that $\mathcal{A}(\tilde{x}^*(\theta_0), \theta_0) \supset \mathcal{A}^*(\theta_0)$ is the active set. Noting that $H\bar{x}^*(\theta_0) = H\tilde{x}^*(\theta_0)$ (follows easily from results in [24]) we get:

$$-(H\tilde{x}^*(\theta_0) + F\theta_0 + c) \quad (16)$$

$$= -(H\bar{x}^*(\theta_0) + F\theta_0 + c) \in N_{\mathcal{P}_0}(\mathcal{A}^*(\theta_0)).$$

■

B. Enforcing uniqueness of the optimizer function

Lemma 2: Consider problem (1). For every $\mathcal{A}^*(\theta_0)$ there is an associated optimal set mapping $X_{\mathcal{A}^*}^* : \Theta_{\mathcal{A}^*} \mapsto 2^{\mathbb{R}^n}$ and the mapping can be represented by

$$\begin{aligned} X_{\mathcal{A}^*}^*(\theta) &\triangleq \{x_{\mathcal{A}^*}^*(\theta, p) \mid \\ &x_{\mathcal{A}^*}^*(\theta, p) \triangleq K_\theta \theta + K_p p + k, \\ &L_{\mathcal{A}^*} (Hx_{\mathcal{A}^*}^*(\theta, p) + F\theta + c) \geq 0, \\ &A_{\mathcal{N}^*} x_{\mathcal{A}^*}^*(\theta, p) \leq b_{\mathcal{N}^*} + S_{\mathcal{N}^*} \theta \}, \end{aligned} \quad (17)$$

where $L_{\mathcal{A}^*}$ defines a normal cone matrix associated with the optimal active set $\mathcal{A}^*(\theta_0)$, K_p is a basis for the null space of $A_{\mathcal{A}^*}$, $K_\theta \in \mathbb{R}^{n \times s}$ and $k \in \mathbb{R}^{n \times 1}$ are constant matrices given by the active set $\mathcal{A}^*(\theta_0)$.

Proof: First part of the proof is to show that

$$x_{\mathcal{A}^*}^*(\theta, p) = K_\theta \theta + K_p p + k \quad (18)$$

defines all solutions to

$$A_{\mathcal{A}^*}x = b_{\mathcal{A}^*} + S_{\mathcal{A}^*}\theta. \quad (19)$$

Assume now that $A_{\mathcal{A}^*}$ does not have full row rank and let $\text{rank}(A_{\mathcal{A}^*}) = m$. Since there exists at least one solution to (19), the system can be reduced to m equations. Applying QR-decomposition $A_{\mathcal{A}^*} = Q \begin{bmatrix} R \\ 0 \end{bmatrix}$ as in [1] we get

$$Rx = b_1 + S_1\theta \quad (20)$$

$$0 = b_2 + S_2\theta \quad (21)$$

where $R \in \mathbb{R}^{m \times n}$ and $\begin{bmatrix} b_1 \\ b_2 \end{bmatrix} = Q^{-1}b_{\mathcal{A}^*}$, $\begin{bmatrix} S_1 \\ S_2 \end{bmatrix} = Q^{-1}S_{\mathcal{A}^*}$. QR-factorization ensures that $\text{rank}(R) = m$, i.e. R has full row rank. We assume that b_2 and S_2 are zero or empty (justified in remark 1).

The null-space method [22] can be applied to systems of equations which have full rank, hence, we have that any solution to (20) can be expressed as the sum of a particular solution and a component in the null space of R , that is,

$$x = Y_R x_Y + Z_R x_Z \quad (22)$$

where Z_R is a basis for the null space of R , and RY_R and $\begin{bmatrix} Y_R & Z_R \end{bmatrix}$ are non-singular. Since $RZ_R = 0$ we have

$$x = Y_R (RY_R)^{-1} (b_1 + S_1\theta) + Z_R x_Z \quad (23)$$

Equation (17) ensures that the negative gradient of (1) is in the normal cone defined by $\mathcal{A}^*(\theta_0)$ and the solution is thereby optimal. Due to (17), $x_{\mathcal{A}^*}(\theta, p)$ is also feasible. ■

Remark 1: When S_2 is non-zero, (21) and the inequalities that ensure feasibility of x define a polyhedron in $\mathbb{R}^w$, $w < s$. As explained in section II-A we are only interested in polyhedra in $\mathbb{R}^s$. See [1] for details.

The matrices Z_R and Y_R in the null space method can be chosen by performing a particular QR-factorization, see [22] for details. We can define the explicit expressions for K_θ , K_p and k

$$K_\theta = Y_R (RY_R)^{-1} S_1, \quad (24)$$

$$K_p = Z_R, \quad (25)$$

$$k = Y_R (RY_R)^{-1} b_1. \quad (26)$$

Proposition 2: K_θ and k defined by equation (24) and (26), respectively, are unique for a given active set $\mathcal{A}^*(\theta_0)$

Proof: All solutions to equation (19) have the same row space component [25]. ■

Lemma 3: Given an optimal active set $\mathcal{A}^*(\theta_0)$ for problem (1) and let the affine function $x_{\mathcal{A}^*}(\theta, p)$ be given by (18) with K_θ , K_p and k defined as in (24)-(26). The following mp-QP

$$v^* \triangleq \min_p \left\{ \frac{1}{2} x_{\mathcal{A}^*}(\theta, p)^T x_{\mathcal{A}^*}(\theta, p) \mid x_{\mathcal{A}^*}(\theta, p) \in X_{\mathcal{A}^*}^*(\theta) \right\}, \quad (27)$$

which is defined for all $\theta \in \Theta_{\mathcal{A}^*}$ and where $X_{\mathcal{A}^*}^*(\theta)$ is the set given by (17), has a unique optimizer $p^*(\theta)$, which is a piecewise affine function of θ .

Proof: Problem (27) can be written as

$$v^* = \min_p \frac{1}{2} p^T H_p p + \theta^T F_{\theta p}^T p + c_p^T p + C, \quad (28a)$$

$$s.t. \quad A_{\mathcal{N}^*}(K_\theta \theta + K_p p + k) \leq b_{\mathcal{N}^*} + S_{\mathcal{N}^*} \theta, \quad (28b)$$

$$L_{\mathcal{A}^*}(H(K_\theta \theta + K_p p + k) + F\theta + c) \geq 0, \quad (28c)$$

where $H_p = K_p^T K_p$, $F_{\theta p}^T = K_\theta^T K_p$, $c_p^T = k^T K_p$, and C is a constant term. Since K_p has linearly independent columns, $K_p^T K_p > 0$, and hence, the mp-QP is strictly convex and the results in the previous section apply. ■

Corollary 1: Any basis K_p for the null space of $A_{\mathcal{A}^*}$ in equation (18) will yield the same optimal $x_{\mathcal{A}^*}(\theta, p^*(\theta))$ in problem (27). Moreover, the product $K_p p^*(\theta)$ is unique regardless of the chosen basis.

Proof: All valid bases K_p will define the same convex set $X_{\mathcal{A}^*}^*(\theta)$. Minimizing the strictly convex function $\frac{1}{2} x_{\mathcal{A}^*}^T(\theta, p) x_{\mathcal{A}^*}(\theta, p)$ must then yield a unique optimal solution $x_{\mathcal{A}^*}(\theta, p^*(\theta))$. Since K_θ , k and $x_{\mathcal{A}^*}(\theta, p^*(\theta))$ are unique regardless of the chosen K_p , so is $K_p p^*(\theta)$. ■

Corollary 2: Let the constraints in (27) be written as

$$\tilde{A}p \leq \tilde{b} + \tilde{S}\theta, \quad (29)$$

Given the optimal active set $\tilde{\mathcal{A}}^*(\theta_0)$ for problem (27) and the associated solution $p_{\tilde{\mathcal{A}}^*}^*(\theta)$, $p_{\tilde{\mathcal{A}}^*}^*(\theta)$ is optimal in the unique region given by

$$R_{\tilde{\mathcal{A}}^*} \triangleq \left\{ \theta \in \Theta \mid \begin{array}{l} \tilde{A}_{\tilde{\mathcal{N}}^*} p_{\tilde{\mathcal{A}}^*}^*(\theta) \leq \tilde{b}_{\tilde{\mathcal{N}}^*} + \tilde{S}_{\tilde{\mathcal{N}}^*} \theta \\ L_{\tilde{\mathcal{A}}^*} (H_p p_{\tilde{\mathcal{A}}^*}^*(\theta) + F_{\theta p} \theta + c_p) \geq 0 \end{array} \right\}, \quad (30)$$

where $L_{\tilde{\mathcal{A}}^*}$ is the normal cone matrix defined by the active set $\tilde{\mathcal{A}}^*(\theta_0)$.

Proof: The optimizer $x_{\mathcal{A}^*}(\theta, p^*(\theta))$, the optimal active set $\tilde{\mathcal{A}}^*(\theta)$, the product $K_p p^*(\theta)$, and the normal cone $L_{\tilde{\mathcal{A}}^*}$ are unique for all $\theta \in \Theta^*$, and Lemma 1 applies. ■

Remark 2: Note that in problem (27) the basis K_p is fixed and consequently $p^*(\theta)$ is dependent on the choice of the basis. However, since $K_p p^*(\theta)$ is unique, the region $R_{\tilde{\mathcal{A}}^*}$ is uniquely defined for all valid bases.

We define the optimal piecewise affine mapping $x^* : \Theta^* \mapsto \mathbb{R}^n$ as

$$x^*(\theta) \triangleq x_{\mathcal{A}^*}(\theta, p_{\tilde{\mathcal{A}}^*}^*(\theta)) \quad \text{if } \theta \in R_{\tilde{\mathcal{A}}^*}. \quad (31)$$

Theorem 4 summarizes the approach and concludes that a unique solution that satisfies Definition 5 is obtained.

Theorem 4 (Uniqueness the solution): Let the affine function $x_{\mathcal{A}^*}(\theta, p)$ be given by (18) with K_θ , K_p and k defined as in (24)-(26) and let $p^*(\theta)$ be found from (27). For any $\theta_0 \in \Theta^*$ there is an associated optimal active set $\mathcal{A}^*(\theta_0)$ and the affine function $x_{\mathcal{A}^*}(\theta, p_{\tilde{\mathcal{A}}^*}^*(\theta))$ is unique and optimal for (1) in the unique polyhedral region given by $R_{\tilde{\mathcal{A}}^*}$. Moreover, the piecewise affine mapping $x^* : \Theta^* \mapsto \mathbb{R}^n$ in (31) obtained by defining full dimensional regions as in (30) is an optimal solution to (1), which satisfies Definition 5.

Proof: Uniqueness of $x_{\mathcal{A}^*}(\theta, p_{\tilde{\mathcal{A}}^*}^*(\theta))$ is fulfilled by construction and proven in Corollary 1. Optimality of $x^*(\theta)$ with respect to (1) is also fulfilled by construction and

is a consequence of Lemma 2 and 3. Uniqueness of the region $R_{\tilde{A}^*}$ follows from Corollary 2. That the solution satisfies Definition 5 follows from uniqueness of $R_{\tilde{A}^*}$. ■

V. ON THE CONTINUITY OF SOLUTIONS TO CONVEX MP-QP

Before we prove that the procedure in section IV-B selects a continuous optimizer function under certain assumptions on the problem data, we restate some definitions from [13]. Let X and Y denote metric spaces in the following three definitions.

Definition 9 (Lower semicontinuous point-to-set map):

The point to set map $P : X \mapsto Y$ is lower semicontinuous at x_0 , if for each open set Ω satisfying $\Omega \cap P(x_0) \neq \emptyset$ there is a neighborhood $U(x_0)$ such that

$$x \in U(x_0) \Rightarrow P(x) \cap \Omega \neq \emptyset. \quad (32)$$

Moreover, P is lower semicontinuous on X if it is lower semicontinuous at each $x \in \text{dom}(P)$.

Definition 10 (Upper semicontinuous point-to-set map):

The point to set map $P : X \mapsto Y$ is upper semicontinuous at x_0 , if for each open set Ω containing $P(x_0)$ there exists a neighborhood $U(x_0)$ such that

$$x \in U(x_0) \Rightarrow P(x) \subset \Omega. \quad (33)$$

Moreover, P is upper semicontinuous on X if it is upper semicontinuous at each $x \in \text{dom}(P)$.

Definition 11 (Continuous point-to-set map): The point to set map $P : X \mapsto Y$ is continuous at x_0 if it is both upper semicontinuous and lower semicontinuous at x_0 . It is continuous on X if and only if it is continuous at every $x \in \text{dom}(P)$.

Theorem 5: Consider problem (1) and let the point to set map $X^*(\theta)$ be continuous on Θ^* . The minimum norm method presented in section IV-B ensures that the optimal mapping $x^* : \Theta^* \mapsto \mathbb{R}^n$ is continuous.

Proof: Let problem (27) be written as

$$v^* \triangleq \min_{x \in \mathbb{R}^n} \left\{ \frac{1}{2} x^T x \mid x \in X^*(\theta) \right\} \quad (34)$$

The minimizer of a strictly convex function over a continuous point to set map is a continuous function [13, Theorem VI.3.3], [26, Corollary 9.3.3]. ■

Since the existence of a continuous selection for problem (1) is ensured by the continuity of $X^*(\theta)$ on Θ^* we state the following corollary based on [7, Theorem 3.2.2, Theorem 3.3.3 and Theorem 5.3.2], which shows that $X^*(\theta)$ is in fact continuous in some cases.

Corollary 3: The consider problem (1). The point to set map $X^*(\theta)$ is continuous on Θ^* if

(i): there does not exist a direction $d \in \mathbb{R}^n \setminus \{0\}$ satisfying

$$Hd = 0 \text{ and } (c + F\theta)^T d = 0, \quad (35)$$

$\forall \theta \in \Theta^*$, or

(ii): $F = 0$.

Proof: Note first that $X^*(\theta)$ is upper semicontinuous on Θ^* [7, Theorem 5.3.2].

(i): By [7, Theorem 3.2.3] $X^*(\theta)$ is lower semicontinuous on Θ^* if the lineality space

$$M = \{d \in \mathbb{R}^n \mid Hd = 0, (c + F\theta)^T d = 0, A_{\mathcal{A}^*} d = 0\} \quad (36)$$

has the same dimension $\forall \theta \in \Theta^*$. If (i) holds, then $\dim(M) = 0, \forall \theta \in \Theta \supseteq \Theta^*$.

(ii): It follows from [7, Theorem 3.3.3] that $X^*(\theta)$ lower semicontinuous on Θ^* . ■

Remark 3: Current research is devoted to obtaining weaker conditions on $f(x, \theta)$ and the constraint set for ensuring the lower semicontinuity of the optimal set mapping. Conditions that involve the assumption that a Slater point exists for the constraint set [6], [7] are not applicable since we are concerned with the set $X^*(\theta) = \{x \in \mathbb{R}^n \mid Ax \leq b + S\theta, f(x, \theta) \leq z^*(\theta)\}$.

VI. EXAMPLE

An example is included to illustrate uniqueness/non-uniqueness of the solution and point (ii) of Corollary 3.

Consider the following convex mp-QP:

$$\begin{aligned} z^* &\triangleq \min_{\{x \in P(\theta) \mid \theta \in \Theta\}} \left\{ \frac{1}{2} x_4^2 - x_1 - x_2 - x_3 + 0.5x_5 \right\}, \\ P(\theta) &\triangleq \left\{ x \in \mathbb{R}^5 \mid \begin{array}{l} x_1 + x_2 + x_3 \leq 10 - \theta_1 - \theta_2 \\ x_1 - 2x_2 \leq 4 - \theta_1 - 2\theta_2 \\ -x_1 - 2x_3 \leq 3 - \theta_1 - 2\theta_2 \\ -x_3 + x_5 \leq 2 + \theta_2 \\ -x_5 \leq 2 + \theta_1 \\ x_4 - x_5 \leq -\theta_1 \\ -3 \leq x_1 \leq 3 \\ -3 \leq x_2 \leq 3 \\ -3 \leq x_3 \leq 3 \end{array} \right\}, \\ \Theta &\triangleq \left\{ \theta \in \mathbb{R}^2 \mid \begin{array}{l} -1 \leq \theta_1 \leq 2.5 \\ 0 \leq \theta_2 \leq 3 \end{array} \right\}. \end{aligned}$$

Since $F = 0$, $X^*(\theta)$ is continuous on Θ^* . The unique set of polytopes obtained by the proposed method is depicted in Figure 1(a), where the subscripts denote which constraints in (1) that are active at the optimum for (27). The constraints are indexed in the order in which they are listed, i.e. $-3 \leq x_1$ is constraint number 7 and $x_1 \leq 3$ is number 8. The optimizer is non-unique in several of the regions in Figure 1(a), and by following the procedure in [2] there are several possible solutions, one of which is depicted in Figure 1(c), where the subscript denotes which constraints that have been arbitrarily selected to construct the regions. Not only is the solution non-unique, but the optimizer is also discontinuous for some selections, see Figure 1(d). By adding $\theta_1 x_5$ to the objective function, neither point (i) nor (ii) in Corollary 3 hold, and consequently $X^*(\theta)$ may not be continuous. By following the proposed method, a unique solution is obtained, however, a continuous solution does not exist, see Figures 1(e)-1(f). It should also be noted that when a bilinear term is present in the objective function, algorithms similar to that of [3] are not applicable, since a region may have more than one neighboring region for each facet, see [27] for a discussion of this topic.

(a) Partition, $F = 0$, proposed method. (b) $x_3^*(\theta)$ continuous, proposed method.

(c) Partition, $F = 0$, arbitrary selection. (d) $x_3^*(\theta)$ discontinuous, arbitrary selection.

(e) Partition, $F \neq 0$, proposed method. (f) $x_3^*(\theta)$ discontinuous, proposed method.

VII. CONCLUSIONS

We have showed that using the normal cone optimality condition to construct critical regions [19] yields a unique and non-intersecting solution for strictly convex mp-QPs. For convex mp-QPs uniqueness of the solution is ensured by choosing the minimum norm optimizer and using the normal cone to characterize the parametric region in which the selection remains optimal.

Global continuity of the piecewise affine optimizer function selected by the proposed method is guaranteed if the optimal set mapping is continuous on the part of the parameter space which renders the solution to the problem feasible and bounded.

VIII. ACKNOWLEDGEMENTS

This research is part of the Strategic University Program on Computational Methods for Nonlinear Motion Control funded by the Research Council of Norway. The second author would like to thank the Research Council of Norway for their support. We also wish to thank Dr. Eric Kerrigan at the Department of Engineering, University of Cambridge, for his comments.
