Linear Programming

 $\begin{array}{l} \min \ c^{T} x \\ \mathrm{s.t.} : A x \leq b \\ x \geq 0 \end{array}$

Remarks:

- Solvable in polynomial-time.
- Efficient algorithms: SIMPLEX and primal-dual interior-point method.

Linear Programming

 $\begin{array}{l} \min \ c^{T} x \\ \mathrm{s.t.} : A x \leq b \\ x \geq 0 \end{array}$

Remarks:

- Solvable in polynomial-time.
- Efficient algorithms: SIMPLEX and primal-dual interior-point method.

Quadratic Programming

$\min \ x^T Q x + c^T x \\ \text{s.t.} : A x \le b$

in which $Q \succ 0$.

Remarks:

Solved efficiently with active-set and interior-point methods.

Quadratic Programming

$$\min \ x^T Q x + c^T x \\ \text{s.t.} : A x \le b$$

in which $Q \succ 0$.

Remarks:

Solved efficiently with active-set and interior-point methods.

Convex Optimization

min
$$f_0(x)$$

s.t.: $Ax = b$
 $f_j(x) \le 0, j = 1, \dots, m$

in which $f_j : \mathbb{R}^n \to \mathbb{R}, j = 0, \dots, m$, are convex functions.

Remarks:

Solved efficiently with interior-point method and Newton's algorithm.

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

Convex Optimization

min
$$f_0(x)$$

s.t.: $Ax = b$
 $f_j(x) \le 0, j = 1, \dots, m$

in which $f_j : \mathbb{R}^n \to \mathbb{R}, j = 0, \dots, m$, are convex functions.

Remarks:

Solved efficiently with interior-point method and Newton's algorithm.

Properties of Convex Programs

- Any local solution x induces a global minimum.
- Any solution that satisfies first-order KKT optimality conditions is a local minimum, and therefore a global minimum.
- Several classes of problems can be shown to be convex.

Continuous Optimization

Mixed-Integer Optimization

Mixed-Integer Nonlinear Optimization

Global Optimization Strategy

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Mixed-Integer Linear Programming

 $\begin{array}{ll} \min \ c_{\mathrm{x}}^{T}x + c_{\mathrm{y}}^{T}y \\ \mathrm{s.t.} : A_{\mathrm{x}}x + A_{\mathrm{y}}y \leq b \\ x \geq 0, \ y \ \mathrm{is \ integer} \end{array}$

Remarks:

- ▶ NP-Hard problem.
- Can be solved in practice with branch-and-bound, branch-and-cut, and other strategies.

Mixed-Integer Linear Programming

$$\begin{array}{ll} \min \ c_{\mathrm{x}}^{T}x + c_{\mathrm{y}}^{T}y \\ \mathrm{s.t.} : A_{\mathrm{x}}x + A_{\mathrm{y}}y \leq b \\ x \geq 0, \ y \ \mathrm{is \ integer} \end{array}$$

Remarks:

- NP-Hard problem.
- Can be solved in practice with branch-and-bound, branch-and-cut, and other strategies.

Mixed-Integer Convex Programming (MICP)

min
$$f_0(x)$$

s.t.: $Ax = b$
 $f_j(x) \le 0, j = 1, \dots, m$

in which $x = (x_{\rm C}, x_{\rm I})$ and $x_{\rm I}$ is integer.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Remarks:

- MILP and MICP are conceptually the same, in the sense that lower bounds can be obtained in polynomial-time.
- If we relax the integrality constraint, MILP becomes an LP and MICP becomes a convex program, both of which can be efficiently computed.

Implications:

- Branch-and-bound can be applied to MICP, much like the way it is applied to MILP.
- Of course, MICP will be much harder and the effectiveness will depend on how fast bounds are computed.

Remarks:

- MILP and MICP are conceptually the same, in the sense that lower bounds can be obtained in polynomial-time.
- If we relax the integrality constraint, MILP becomes an LP and MICP becomes a convex program, both of which can be efficiently computed.

Implications:

- Branch-and-bound can be applied to MICP, much like the way it is applied to MILP.
- Of course, MICP will be much harder and the effectiveness will depend on how fast bounds are computed.

Difficulties:

- For MILP, the dual Simplex algorithm provides hot start optimization from infeasible solutions produced by branch-and-bound.
 - Introducing a bound on a variable renders the current dictionary infeasible in the primal, but suboptimal in the dual.
 - a constraint in the primal becomes a variable in the dual.
- Such hot start mechanisms are not generally available for convex problems.

Difficulties:

- For MILP, the dual Simplex algorithm provides hot start optimization from infeasible solutions produced by branch-and-bound.
 - Introducing a bound on a variable renders the current dictionary infeasible in the primal, but suboptimal in the dual.
 - a constraint in the primal becomes a variable in the dual.
- Such hot start mechanisms are not generally available for convex problems.

Much of the literature explores the problem structure:

- Bonmin is a general solver for MICP.
- CPLEX can handle Mixed-Integer Quadratically Constrained Programs, in which the quadratic functions are convex.

Mixed-Integer Nonlinear Optimization

Global Optimization Strategy

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

The general MINLP is a problem of the form:

```
min f(x)
s.t.: g_j(x) \le 0, j = 1, ..., p
h_j(x) = 0, j = 1, ..., q
```

in which $x = (x_{\rm C}, x_{\rm I})$ and $x_{\rm I}$ is integer.

Remarks:

- ▶ Very hard problem, for which there does not exist general methods.
- Can be solved for particular problems, and particular sizes.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ ● ●

The general MINLP is a problem of the form:

```
\begin{array}{l} \min \ f(x) \\ \mathrm{s.t.} : g_j(x) \leq 0, \, j = 1, \dots, p \\ h_j(x) = 0, \, j = 1, \dots, q \end{array}
```

in which $x = (x_C, x_I)$ and x_I is integer.

Remarks:

- Very hard problem, for which there does not exist general methods.
- Can be solved for particular problems, and particular sizes.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ ● ●

What will we do here?

- We address the general class in which the nonlinear terms are bilinear.
- For instance, $x \cdot y$, x^2 , etc.
- Several applications are found in theory and practice.

What will we do here?

- We address the general class in which the nonlinear terms are bilinear.
- For instance, $x \cdot y$, x^2 , etc.
- Several applications are found in theory and practice.

Bilinear Optimization: Polynomials

- Polynomials can be converted into bilinear models.
- For instance,

$$f(x_1, x_2, x_3) = x_1^2 x_2 x_3$$

can be converted to

$$f = w_{1,1} \cdot w_{2,3}$$
$$w_{1,1} = x_1^2$$
$$w_{2,3} = x_2 x_3$$

Bilinear Optimization: Blending

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

Bilinear Optimization: Blending

For stable operations, the ratio of the "qualities" are held constant:

$$rac{q_i}{q} = rac{\Delta q_i}{\Delta q} \Longleftrightarrow q_i \cdot \Delta q = \Delta q_i \cdot q$$

in which:

- q is the volume of the mixture in the tank.
- \mathbf{p}_i is the volume of a product *i* in the mixture.
- Δq is the volume being pumped out.
- Δq_i is the volume of quality *i* being pumped out.

Bilinear Optimization: Blending

For stable operations, the ratio of the "qualities" are held constant:

$$rac{q_i}{q} = rac{\Delta q_i}{\Delta q} \Longleftrightarrow q_i \cdot \Delta q = \Delta q_i \cdot q$$

in which:

- q is the volume of the mixture in the tank.
- q_i is the volume of a product i in the mixture.
- Δq is the volume being pumped out.
- Δq_i is the volume of quality *i* being pumped out.

Bilinear Optimization: Modeling Trigonometric Functions

Polar coordinates,

 $x = r\cos(\theta)$ $y = r\sin(\theta)$

can be represented in Cartesian form

 $x^2 + y^2 = r^2$

without the need of trigonometric functions.

Consider the bilinear function

w = xy

and suppose that bounds are known:

 $x^{L} \le x \le x^{U}$ $y^{L} \le y \le y^{U}$

First we manipulate the bounds

$$\begin{aligned} x - x^{L} &\ge 0 & y - y^{L} &\ge 0 \\ x^{U} - x &\ge 0 & y^{U} - y &\ge 0 \end{aligned}$$

Mulitplying the first of each bound, we obtain

$$(x - x^{L})(y - y^{L}) \ge 0 \iff xy - xy^{L} - yx^{L} + x^{L}y^{L} \ge 0$$
$$\iff w \ge xy^{L} + yx^{L} - x^{L}y^{L}$$

which is a linear inequality.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

First we manipulate the bounds

$$\begin{array}{ll} x - x^{L} \geq 0 & y - y^{L} \geq 0 \\ x^{U} - x \geq 0 & y^{U} - y \geq 0 \end{array}$$

Mulitplying the first of each bound, we obtain

$$(x - x^{L})(y - y^{L}) \ge 0 \iff xy - xy^{L} - yx^{L} + x^{L}y^{L} \ge 0$$
$$\iff w \ge xy^{L} + yx^{L} - x^{L}y^{L}$$

which is a linear inequality.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

The underestimators of the function are represented by:

 $w \ge x^{L}y + xy^{L} - x^{L}y^{L}$ $w \ge x^{U}y + xy^{U} - x^{U}y^{U}$

▶ The overestimators of the function are represented by:

 $w \le x^U y + xy^L - x^U y^L$ $w \le xy^U + x^L y - x^L y^U$

The underestimators of the function are represented by:

$$w \ge x^{L}y + xy^{L} - x^{L}y^{L}$$
$$w \ge x^{U}y + xy^{U} - x^{U}y^{U}$$

The overestimators of the function are represented by:

$$w \le x^U y + xy^L - x^U y^L$$
$$w \le xy^U + x^L y - x^L y^U$$

McCormick Envelopes

What do we gain from McCormick Envelopes?

Consider an NLP with only bilinear terms.

- Replacing the bilinear terms with McCormick Envelopes converts the NLP into an LP.
- The LP solution gives us a lower bound.
- Any feasible solution gives us an upper bound.

For an MINLP with only bilinear terms.

- Replacing the bilinear terms with McCormick Envelopes renders MINLP an MILP.
- The MILP solution gives us a lower bound.
- Any feasible solution gives us an upper bound.

What if we improve the bounds iteratively?

We can produce a series of increasing lower bounds: w^{L,k}, k = 0, 1, ...

• And a series of decreasing upper bounds: $w^{U,k}$, k = 0, 1, ...

so that:

$$w^{L,0} \le w^{L,1} \le \dots \le w^{L,k}$$
$$w^{U,0} \ge w^{U,1} \ge \dots \ge w^{U,k}$$

and we stop when $w^{U,k} - w^{L,k} \le \epsilon$

What if we improve the bounds iteratively?

- We can produce a series of increasing lower bounds: w^{L,k}, k = 0, 1, ...
- And a series of decreasing upper bounds: $w^{U,k}$, k = 0, 1, ...

so that:

$$w^{L,0} \le w^{L,1} \le \dots \le w^{L,k}$$
$$w^{U,0} \ge w^{U,1} \ge \dots \ge w^{U,k}$$

and we stop when $w^{U,k} - w^{L,k} \le \epsilon$.

What if we improve the bounds iteratively?

- We can produce a series of increasing lower bounds: w^{L,k}, k = 0, 1, ...
- And a series of decreasing upper bounds: $w^{U,k}$, k = 0, 1, ...

so that:

$$w^{L,0} \le w^{L,1} \le \dots \le w^{L,k}$$
$$w^{U,0} \ge w^{U,1} \ge \dots \ge w^{U,k}$$

and we stop when $w^{U,k} - w^{L,k} \leq \epsilon$.

Problem Definition

 $\begin{array}{l} \min \ f_0(x) \\ \text{s.t.} : f_q(x) \leq 0, \ q \in \mathcal{Q} \setminus \{0\} \\ f_q(x) = \sum_{(i,j) \in \mathcal{BL}} a_{i,j,q} x_i x_j + h_q(x), \ q \in \mathcal{Q} \\ x^L \leq x \leq x^U \\ x \in \mathbb{R}^m \end{array}$

In case of an NLP, an LP relaxation is derived by replacing each bilinear term with a new variable:

 $w_{ij} = x_i \cdot x_j$

and adding four sets of constraints.

In case of an MINLP, an MILP relaxation is derived.

This strategy is known as McCormick relaxation.

In case of an NLP, an LP relaxation is derived by replacing each bilinear term with a new variable:

 $w_{ij} = x_i \cdot x_j$

and adding four sets of constraints.

In case of an MINLP, an MILP relaxation is derived.

This strategy is known as McCormick relaxation.

In either case (NLP or MINLP), a tighter MILP relaxation can be obtained as follows:

- Partition the domain of one of the variables, let us say x_j of the bilinear term into n disjoint regions.
- Add new binary variables to the formulation to select the optimal partition x_j.

This strategy is known as piecewise McCormick relaxation.

This strategy is known as piecewise McCormick relaxation.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

- Let x_{in}^L and x_{in}^U be lower and upper bounds for x_j in partition *n*.
- ► If the value of x_j does belong to such a partition, then the binary variable y_{jn} = 1 and the McCormick envelope hold.
- The piecewise McCormick relaxation can be formulated as a Generalized Disjunctive Program (Raman and Grossmann, 1994).
- PR-GDP is tighter because the use of partition-dependent x^L_{jn} and x^U_{jn} inside the disjunction, instead of the global bounds x^L_i and x^U_i.
