## Summary

#### Introduction

Relaxations

Lagrangian Relaxation

- Optimality Conditions: How do we assess the quality of a given candidate solution with respect the optimum, without knowing the optimum?
- This can be achieved by solving an easier problem to optimality, however within a space that includes the feasible space of the problem at hand.

- Optimality Conditions: How do we assess the quality of a given candidate solution with respect the optimum, without knowing the optimum?
- This can be achieved by solving an easier problem to optimality, however within a space that includes the feasible space of the problem at hand.

Relaxations can be obtained by:

- disconsidering some constraints;
- neglecting the integrality of discrete variables;
- solving a simplified problem.

#### Take the following Integer Program:

$$IP: z = \max \{ c^{\mathrm{T}} x : x \in X \subseteq \mathbb{Z}^n \}$$

- Given a candidate solution x\*, how can we prove that x\* is an optimal solution?
- We look for optimality conditions that provide a stopping condition for algorithms.

- One method consists of finding a lower bound <u>z</u> ≤ z and an upper bound <u>z</u> ≥ z such that <u>z</u> = <u>z</u>, in which case z is the optimum.
- ▶ Typically, an algorithm produce two sequences of bounds:
  - a sequence of upper bounds  $\overline{z}_1 > \overline{z}_2 > \ldots > \overline{z}_t \ge z$
  - ▶ a sequence of lower bounds  $\underline{z}_1 < \underline{z}_2 < \ldots < \underline{z}_k \leq z$ .
- Given  $\xi \ge 0$ , we can define a stopping criterion such as  $|\overline{z}_t \underline{z}_k| \le \xi$ .

- One method consists of finding a lower bound <u>z</u> ≤ z and an upper bound <u>z</u> ≥ z such that <u>z</u> = <u>z</u>, in which case z is the optimum.

- Given ξ ≥ 0, we can define a stopping criterion such as |z<sub>t</sub> − <u>z<sub>k</sub></u>| ≤ ξ.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ ● ●

- When an algorithm terminates, the conditions ascertain that the candidate solution z is at most ξ units worse than the optimum.
- The ability to estimate the quality of a candidate solution is of fundamental importance in optimization.

- When an algorithm terminates, the conditions ascertain that the candidate solution z is at most ξ units worse than the optimum.
- The ability to estimate the quality of a candidate solution is of fundamental importance in optimization.

Finding a feasible solution may be a hard or easy task. It is a problem dependent issue.

- Any feasible solution x, x ∈ X, induces a bound (lower bound for maximization) given that c<sup>T</sup>x ≤ c<sup>T</sup>x<sup>\*</sup> = z<sup>\*</sup>.
- For NP-Complete problems, the search for a feasible solution corresponds to solving the problem.
- On the other hand, finding a feasible route for the traveling salesman probllem is easy, the hardness being in reaching the shortest route.

## Dual Bound

- A method to find an upper bound relies on a relaxation of the problem at hand.
- That is, a simpler problem whose optimal solution has an objective value not inferior to the optimum of the problem of concern.

## **Dual Bound**

#### Definition A problem *R*:

$$z^{\mathrm{R}} = \max \{f(x) : x \in T \subseteq \mathbb{R}^n\}$$

is a relaxation of the problem IP:

$$z = \max \{ c(x) : x \in X \subseteq \mathbb{R}^n \}$$

#### if:

i)  $X \subseteq T$ ii)  $f(x) \ge c(x)$  for all  $x \in X$ .

## Summary

Introduction

Relaxations

Lagrangian Relaxation

・ロ> < 回> < 三> < 三> < 三> < 回> < 回> < <</li>

## Linear Relaxation

#### Linear Relaxation

For the integer programming problem:

 $\max \{ c^{\mathrm{T}} x : x \in P \cap \mathbb{Z}^n \}$ 

with formulation:

$$P = \{x \in \mathbb{R}^n_+ : Ax \le b\}$$

the linear relaxation is:

$$z^{\mathrm{PL}} = \max \{ c^{\mathrm{T}} x : x \in P \}$$

#### Linear Relaxation

#### Example

$$z = \max 4x_1 -x_2$$
  
s.t.:  $7x_1 -2x_2 \le 14$   
 $x_2 \le 3$   
 $2x_1 -2x_2 \le 3$ 

where  $x \in \mathbb{Z}^2_+$ .

• Lower bound: notice that  $\underline{x} = (2, 1)$  is feasible, therefore  $z \ge 7$ .

▲□▶ ▲圖▶ ▲ 臣▶ ▲ 臣▶ ― 臣 … のへぐ

### Linear Relaxation

#### Example

$$z = \max 4x_1 -x_2$$
  
s.t.:  $7x_1 -2x_2 \le 14$   
 $x_2 \le 3$   
 $2x_1 -2x_2 \le 3$ 

where  $x \in \mathbb{Z}^2_+$ .

► Lower bound: notice that <u>x</u> = (2,1) is feasible, therefore z ≥ 7.

▲□▶ ▲圖▶ ▲ 臣▶ ▲ 臣▶ ― 臣 … のへぐ

### Linear Relaxation

#### Example

$$z = \max \begin{array}{ccc} 4x_1 & -x_2 \\ \text{s.t.} & 7x_1 & -2x_2 & \leq & 14 \\ & x_2 & \leq & 3 \\ 2x_1 & -2x_2 & \leq & 3 \end{array}$$

where  $x \in \mathbb{Z}^2_+$ .

▶ Upper bound: an optimal solution to the linear relaxation  $x^* = \left(\frac{20}{7}, 3\right)$  with  $z^{\text{LP}} = \frac{59}{7}$ , thus one concludes that  $z \le 8 \le \frac{59}{7}$ , in which  $8 = \lfloor \frac{59}{7} \rfloor$ .

### Linear Relaxation

#### Example

$$z = \max 4x_1 -x_2$$
  
s.t.:  $7x_1 -2x_2 \le 14$   
 $x_2 \le 3$   
 $2x_1 -2x_2 \le 3$ 

where  $x \in \mathbb{Z}^2_+$ .

▶ Upper bound: an optimal solution to the linear relaxation  $x^* = \left(\frac{20}{7}, 3\right)$  with  $z^{\text{LP}} = \frac{59}{7}$ , thus one concludes that  $z \le 8 \le \frac{59}{7}$ , in which  $8 = \lfloor \frac{59}{7} \rfloor$ .

### Combinatorial Relaxation

- When the relaxation consists of a combinatorial problem, the relaxation is said to be a combinatorial relaxation.
- An example of a combinatorial relaxation for the traveling salesman problem and the knapsack problem are given below.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

# The Traveling Salesman Problem (TSP)

min  $\sum_{i=1}^n \sum_{j=1}^n c_{ij} x_{ij}$ (1)n

s.t.: 
$$\sum_{j=1} x_{ij} = 1$$
  $i = 1, .., n$  (2)

$$\sum_{i=1}^{n} x_{ij} = 1 \qquad j = 1, .., n \tag{3}$$

$$\sum_{i\in S}\sum_{j\notin S} x_{ij} \ge 1 \qquad \forall S \subset \{1,\ldots,n\}, |S| \ge 2$$
(4)

 $x_{ij} \in \{0,1\}$   $\forall (i,j) \in A$ (5)

## The Traveling Salesman Problem

- Discarding the family (4) of constraints, the allocation problem is obtained.
- Notice that the allocation problem can be solved efficiently.

### The Knapsack Problem

$$\begin{array}{ll} (\mathcal{KP}) & \max & \sum\limits_{j=1}^n c_j x_j \\ & \mathrm{s.t.:} & \sum\limits_{j=1}^n a_j x_j \leq b \\ & x_j \in \{0,1\}, j=1,\ldots,n \end{array}$$

◆□▶ ◆□▶ ◆ 臣▶ ◆ 臣▶ ○ 臣 ○ の Q @

-Relaxations

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Combinatorial Relaxation

## The Knapsack Problem

A first relaxation is obtained if we take the integers immediately inferior to the weights of the items:

$$(RP_1) \max \sum_{\substack{j=1 \\ j=1}}^{n} c_j x_j$$
  
s.t.: 
$$\sum_{\substack{j=1 \\ j=1}}^{n} \lfloor a_j \rfloor x_j \le b$$
  
$$x_j \in \{0, 1\}, j = 1, \dots, n$$
(6)

## The Knapsack Problem

The above relaxation is equivalent to the problem:

$$(RP_2) \max \sum_{j=1}^{n} c_j x_j$$
  
s.t.: 
$$\sum_{j=1}^{n} \lfloor a_j \rfloor x_j \le \lfloor b \rfloor$$
  
$$x_j \in \{0, 1\}, j = 1, \dots, n$$

$$(7)$$

# Summary

Introduction

Relaxations

Lagrangian Relaxation

・ロ> < 回> < 三> < 三> < 三> < 回> < 回> < <</li>

First, consider the general integer program given by:

$$\begin{array}{ll} (P) & z = & \max \ c^{\mathrm{T}}x \\ & \mathrm{s.t.}: \ Ax \leq b \\ & x \in \mathcal{X} \subseteq \mathbb{Z}^r \end{array}$$

As seen above, a relaxation is obtained if we neglect the constraints  $\{Ax \leq b\}$ .

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Rather than discarding  $\{Ax \le b\}$ , the Lagrangian relaxation introduces these constraints in the objective:

$$LR(u) \quad z = \max c^{\mathrm{T}}x + u^{\mathrm{T}}(b - Ax)$$
  
s.t.:  $x \in \mathcal{X}$   
 $u \ge 0$ 

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

#### Proposition

- Let  $z(u) = \max \{ c^{\mathrm{T}}x + u^{\mathrm{T}}(b Ax) : x \in X \}.$
- Then  $z(u) \ge z$  for all  $u \ge 0$ .

## Lagrangian Relaxation: Remarks

- Given u ≥ 0, the optimal solution to (LR) induces an upper bound z(u) ≥ z\*.
- We can verify that  $z(u) \ge c^{\mathrm{T}}x$ , for all  $x \in \mathcal{P} = \{x : x \in X \in Ax \le b\}$ :
  - ▶  $c^{\mathrm{T}}x \leq c^{\mathrm{T}}x + u^{\mathrm{T}}(b Ax)$  since  $b Ax \geq 0$ , x is feasible, and  $u \geq 0$ ;
  - Since the feasible solution to the integer program (IP) is also within the feasible space of LR, we conclude that z(u) ≥ z\*.

## Lagrangian Relaxation: Remarks

- Given u ≥ 0, the optimal solution to (LR) induces an upper bound z(u) ≥ z\*.
- We can verify that  $z(u) \ge c^{\mathrm{T}}x$ , for all  $x \in \mathcal{P} = \{x : x \in X \text{ e } Ax \le b\}$ :
  - $c^{\mathrm{T}}x \leq c^{\mathrm{T}}x + u^{\mathrm{T}}(b Ax)$  since  $b Ax \geq 0$ , x is feasible, and  $u \geq 0$ ;
  - Since the feasible solution to the integer program (IP) is also within the feasible space of LR, we conclude that z(u) ≥ z\*.

#### Convexity of Dual Function

Take  $u, v \ge 0$  and  $\theta \in [0, 1]$ . Then

$$z(\theta u + (1 - \theta)v) = \max_{x \in \mathcal{X}} c^{\mathrm{T}}x + (\theta u + (1 - \theta)v)^{\mathrm{T}}(b - Ax)$$
  
$$= \max_{x \in \mathcal{X}} c^{\mathrm{T}}(\theta + (1 - \theta))x + (\theta u + (1 - \theta)v)^{\mathrm{T}}(b - Ax)$$
  
$$= \max_{x \in \mathcal{X}} \theta[c^{\mathrm{T}}x + u^{\mathrm{T}}(b - Ax)] + (1 - \theta)[c^{\mathrm{T}}x + v^{\mathrm{T}}(b - Ax)]$$
  
$$\leq \theta \cdot \max_{x \in \mathcal{X}} [c^{\mathrm{T}}x + u^{\mathrm{T}}(b - Ax)] + (1 - \theta) \cdot \max_{x \in \mathcal{X}} [c^{\mathrm{T}}x + v^{\mathrm{T}}(b - Ax)]$$
  
$$= \theta z(u) + (1 - \theta)z(v)$$

▲□▶ ▲圖▶ ▲ 臣▶ ▲ 臣▶ ― 臣 … のへぐ

## Lagrangian Dual

Since z(u) is an upper bound for  $z^*$ , naturally one would wish to minimize the upper bound, giving rise to the Lagrangian Dual:

 $\begin{array}{rcl} LD: & \min & z(u) & \cong & \min & \max & c^{\mathrm{T}}x + u^{\mathrm{T}}(b - Ax) \\ & u \geq 0 & & u \geq 0 \\ & & & \mathrm{s.t.:} & x \in \mathcal{X} \end{array}$ 

#### Lagrangian Dual

- The Lagrangian dual is convex but not a differentiable problem.
- An approximate solution for *LD* could be sought.
- Under certain conditions, an optimal solution can be found using the subgradient algorithm.

# Subgradient

#### Definition

Given a function  $z : \mathbb{R}^n \to \mathbb{R}$ , a vector  $d(u) \in \mathbb{R}^n$  is a subgradient for z at  $u \in U$  if:

$$z(v) \geq z(u) + d(u)^{\mathrm{T}}(v-u), \, \forall v \in \mathcal{U}$$

in which  $\mathcal{U}$  is the domain of z.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

# Subgradient

► Take u ≥ 0 for LD, and let x(u) ∈ X be the point that induces the value z(u).

▶ Then, a subgradient for *z* at *u* is given by:

d(u) = b - Ax(u)

because z(u) is a convex function in u.

# Subgradient

- ► Take u ≥ 0 for LD, and let x(u) ∈ X be the point that induces the value z(u).
- Then, a subgradient for z at u is given by:

d(u) = b - Ax(u)

because z(u) is a convex function in u.

## Subgradient Algorithm

- 1. Input parameters:  $u_0 \ge 0$ ,  $\mu_0$ , and  $\rho < 1$ .
- 2. Let k = 0.
- 3. Compute  $z(u_k)$  and obtain  $x(u_k)$  by solving  $LR(u_k)$ .
- 4. If  $x(u_k)$  is feasible for IP, or stopping criteria is satisfied, then halt.
- 5. Let  $d_k = b A_x(u_k)$  be the subgradient.
- $6. \quad u_{k+1} = u_k \mu_k d_k.$
- 7.  $\mu_{k+1} = \rho \mu_k$ , k = k + 1, and repeat from step 3.

### Lagrangian Dual as an LP Program

Example: Consider the following instance of the knapsack problem:

$$z = \max 10x_1 + 7x_2 + 25x_3 + 24x_4$$
  
s.t.:  $2x_1 + x_2 + 6x_3 + 5x_4 \le 7$   
 $x_1, x_2, x_3, x_4 \in \{0, 1\}$ 

Challenge: develop an LP program equivalent to the Lagrangian Dual.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

### Lagrangian Dual as an LP Program

Example: Consider the following instance of the knapsack problem:

$$z = \max 10x_1 + 7x_2 + 25x_3 + 24x_4$$
  
s.t.:  $2x_1 + x_2 + 6x_3 + 5x_4 \le 7$   
 $x_1, x_2, x_3, x_4 \in \{0, 1\}$
