(Keynote Lecture at the 5th EUROMECH Nonlinear Dynamics Conference)

This article presents a unified state-space model for ship maneuvering, station-keeping, and control in a seaway. The frequency-dependent potential and viscous damping terms, which in classic theory results in a convolution integral not suited for real-time simulation, is compactly represented by using a state-space formulation. The separation of the vessel model into a low-frequency model (represented by zero-frequency added mass and damping) and a wave-frequency model (represented by motion transfer functions or RAOs), which is commonly used for simulation, is hence made superfluous.

Keywords: ship modelling, equations of motion, hydrodynamics, maneuvering, seakeeping, autopilots, dynamic positioning.

1 Introduction

Motivated by the work of Bishop and Price [1981] and Bailey et al. [1998], a unified state-space model for ship maneuvering, station-keeping, and control in a seaway is derived. The dynamic equations of motion for a ship exposed to waves have evolved from two main directions:

- Maneuvering theory
- Seakeeping theory

In maneuvering theory it is common to assume that the ship is moving in restricted calm water, e.g. in sheltered waters or in a harbor. Hence, the ship model is derived for a ship moving at positive speed \( U \) under a zero-frequency assumption such that added mass and damping can be represented by using hydrodynamic derivatives. Seakeeping analysis is used in operability calculations to obtain operability diagrams according to the adopted criteria. It also refers to the motions of a vessel in waves usually at a specific speed (including station-keeping, i.e. zero speed) and heading in a sinusoidal, irregular or random seaway. This includes analyses of motions in the time-domain for frequency-dependent added mass and damping.

It is desirable to unify these theories such that the ship motions can be described more accurately for different speeds, sea states, and operations. This should be done in the time-domain in order to facilitate performance tests and design of feedback control systems. Another application is real-time training simulators. For this purpose we will discuss a:

- Unified time-domain theory for maneuvering and seakeeping

where it is possible to include systems for feedback control, that is autopilots, dynamic positioning systems, roll damping systems etc.

The unified model will be derived using a state-space approach since this is the standard representation used in feedback control systems.

The kinematic and dynamic equations of motion for ships are presented using principles from the classical maneuvering and seakeeping theories. The relationship between frequency-dependent oscillatory derivatives, hydrodynamic derivatives, and frequency dependent hydrodynamic coefficients are explained through examples. The final unified model is represented in the time-domain as a 6 degree-of-freedom (DOF) nonlinear state-space model. The state-space model is written in a compact matrix-vector setting such that structural properties like symmetry, skew-symmetry, positive definiteness, passivity etc. can be exploited when designing control systems.

The state-space models are used as basis for development of 3 DOF (surge, sway, and yaw) nonlinear dynamic
positioning systems for station-keeping and low-speed maneuvering of ships and rigs. Autopilot design in 1 DOF for ships moving at moderate speed is also discussed. The model parameters for floating vessels can be computed using commercial 2D potential theory programs. The details regarding this are presented in the case study.

Feedback control systems design for ships goes back to the invention of the North-seeking gyroscope in 1908 by Anschütz, the ballistic gyroscope in 1911 by Sperry [Allensworth, 1999], and the analysis of the three-term PID-controller [Minorsky, 1922]. These developments were fundamental for the evolution of modern model-based ship control systems for station-keeping and maneuvering. More recently, the development of global satellite navigation systems and inertial measurements technology have further contributed to the design of highly sophisticated nonlinear model-based ship control systems. From a historical point of view, the PID-controller was the dominating design technique until the invention of the Kalman filter and the linear quadratic optimal controller (LQG) in the 1960s.

Motivated by this Balchen et al. [1976] proposed to model the wave-induced disturbances as 2nd-order oscillators in the Kalman estimator in order to filter out 1st-order wave-induced disturbances from the feedback loop. This technique is today known as wave filtering, and it replaced the notch filter in dynamic positioning (DP) systems and autopilots. The concept of wave filtering has further been refined using linear H-infinity controllers with frequency-dependent weighting. This allows the designer to put penalties on the wave-induced disturbances in a limited frequency range. Nonlinear ship control systems became popular in the 1990s using Lyapunov methods for stability analyses [Fossen, 1994, 2002].

2 Notation and Other Preliminaries

The notation used in this paper complies with SNAME [1950], see Table 1.

2.1 Degrees of Freedom

In maneuvering, a marine vessel experiences motion in 6 degrees-of-freedom (DOF). The motion in the horizontal plane is referred to as surge (longitudinal motion, usually superimposed on the steady propulsive motion) and sway (sideways motion). Heading, or yaw (rotation about the vertical axis) describes the course of the vessel. The remaining three DOFs are roll (rotation about the longitudinal axis), pitch (rotation about the transverse axis), and heave (vertical motion), see Figure 1.

Roll is probably the most troublesome DOF, since it produces the highest accelerations and, hence, is the principal villain in seasickness. Similarly, pitching and heaving feel uncomfortable to humans. When designing ship autopilots, yaw is the primary mode for feedback control.

![Figure 1: Definitions of ship motions in the b-frame.](image-url)

2.2 Generalized Position, Velocity and Force

The generalized position, velocity, and force vectors are defined according to Fossen [1994, 2002]:

\[ \eta = [n, e, d, \phi, \theta, \psi]^T \in \mathbb{R}^3 \times \mathbb{S}^3 \]  
\[ \nu = [u, v, w, p, q, r]^T \in \mathbb{R}^6 \]  
\[ \tau = [X, Y, Z, K, M, N]^T \in \mathbb{R}^6 \]

where the Euler angles can be conveniently represented by the vector:

\[ \Theta = [\phi, \theta, \psi]^T \in \mathbb{S}^3 \]

The North-East-Down position vector is denoted as

\[ p = [n, e, d]^T \in \mathbb{R}^3 \]

The Euclidean space of dimension n is denoted \( \mathbb{R}^n \) while \( \mathbb{S}^2 \) denotes a torus of dimension 2 (shape of a donut) implying that there are two angles defined on the interval \([0, 2\pi]\). In the 3-dimensional case the set is denoted as \( \mathbb{S}^3 \).

2.3 Oscillatory and Hydrodynamic Derivatives

The frequency-dependent oscillatory derivatives are written as [Bailey et al., 1998]:

\[ \tilde{F}_{ij}(\omega) - \text{oscillatory derivative} \]
where $F$ is the generalized force, $\beta$ is the motion component:

$$ F \in \{X, Y, Z, K, M, N\} $$

and $\omega$ is the frequency of oscillation. Examples of oscillatory derivatives are:

$$ \dot{Y}_\omega(\omega), \quad N_\omega(\omega), \quad \ddot{K}_p(\omega), \text{ etc.} \quad \text{(7)} $$

These derivatives are frequency dependent and they can be derived from maneuvering based PMM experiments [Gertler, 1959], [Chislett and Strom-Tejens, 1965].

The limiting value for $\omega = 0$ is defined as the hydrodynamic derivative, that is:

$$ F_\beta \triangleq \frac{\partial F}{\partial \beta} \triangleq \tilde{F}_\beta(0) \quad \text{hydrodynamic derivative} \quad \text{(8)} $$

For instance, the hydrodynamic derivative $Y_\dot{w}$ corresponds to a force $Y$ in the $y$-direction due to an acceleration $\dot{w}$ in the $z$-direction, while the hydrodynamic derivative $K_p$ corresponds to the moment $K$ due to an angular velocity $p$ about the $x$-axis. This suggests [SNAME, 1950]:

$$ Y_{\dot{w}} \triangleq \frac{\partial Y}{\partial \dot{w}}, \quad K_p \triangleq \frac{\partial K}{\partial p} \quad \text{(9)} $$

The resulting force and moment are then:

$$ Y = Y_{\dot{w}} \dot{w}, \quad K = K_p p \quad \text{(10)} $$

The 6 DOF generalized mass and damping matrices in terms of oscillatory derivatives are denoted as $M_A(\omega)$ and $D(\omega)$, while the matrices:

$$ M_A \triangleq \bar{M}_A(0) \quad \text{(11)} $$

$$ D \triangleq \bar{D}(0) \quad \text{(12)} $$

for the slow motion hydrodynamic derivatives take the following form [Fossen, 1994, 2002]:

$$ M_A = \begin{bmatrix}
X_\dot{u} & X_\dot{v} & X_\dot{w} & X_\dot{p} & X_\dot{q} & X_\dot{r} \\
Y_\dot{u} & Y_\dot{v} & Y_\dot{w} & Y_\dot{p} & Y_\dot{q} & Y_\dot{r} \\
Z_\dot{u} & Z_\dot{v} & Z_\dot{w} & Z_\dot{p} & Z_\dot{q} & Z_\dot{r} \\
K_\dot{u} & K_\dot{v} & K_\dot{w} & K_\dot{p} & K_\dot{q} & K_\dot{r} \\
M_\dot{u} & M_\dot{v} & M_\dot{w} & M_\dot{p} & M_\dot{q} & M_\dot{r} \\
N_\dot{u} & N_\dot{v} & N_\dot{w} & N_\dot{p} & N_\dot{q} & N_\dot{r}
\end{bmatrix} \quad \text{(13)} $$

$$ D = \begin{bmatrix}
X_\ddot{u} & X_\ddot{v} & X_\ddot{w} & X_\ddot{p} & X_\ddot{q} & X_\ddot{r} \\
Y_\ddot{u} & Y_\ddot{v} & Y_\ddot{w} & Y_\ddot{p} & Y_\ddot{q} & Y_\ddot{r} \\
Z_\ddot{u} & Z_\ddot{v} & Z_\ddot{w} & Z_\ddot{p} & Z_\ddot{q} & Z_\ddot{r} \\
K_\ddot{u} & K_\ddot{v} & K_\ddot{w} & K_\ddot{p} & K_\ddot{q} & K_\ddot{r} \\
M_\ddot{u} & M_\ddot{v} & M_\ddot{w} & M_\ddot{p} & M_\ddot{q} & M_\ddot{r} \\
N_\ddot{u} & N_\ddot{v} & N_\ddot{w} & N_\ddot{p} & N_\ddot{q} & N_\ddot{r}
\end{bmatrix} \quad \text{(14)} $$

Notice that the matrices are multiplied with $-1$ such that $M_A > 0$ and $D > 0$ (positive mass and damping).

### 2.4 Generalized Rigid-Body Inertia Matrix

The generalized rigid-body inertia matrix is defined as [Fossen, 1994, 2002]:

$$ M_{RB} = \begin{bmatrix}
mI_{3\times3} & -mS(r^b) \\
mS(r^b) & I_o
\end{bmatrix} \quad \text{(15)} $$

where $m$ is the mass, $I_{3\times3} \in \mathbb{R}^{3\times3}$ is the identity matrix, $r^b = [x_g, y_g, z_g]^T$ are the coordinates to the center of gravity with respect to the point $O$ in the body-fixed reference frame, and:

$$ I_o = \begin{bmatrix}
I_x & -I_{xy} & -I_{xz} \\
-I_{xy} & I_y & -I_{yz} \\
-I_{xz} & -I_{yz} & I_z
\end{bmatrix} \quad \text{(16)} $$

is the inertia tensor. For notational simplicity the vector cross product:

$$ a \times b = S(a)b \quad \text{(17)} $$

is written in terms of a skew-symmetric matrix $S \in \mathbb{S} \mathbb{S}(3)$ defined as:

$$ S(\lambda) = -S^T(\lambda) = \begin{bmatrix}
0 & -\lambda_3 & \lambda_2 \\
\lambda_3 & 0 & -\lambda_1 \\
-\lambda_2 & \lambda_1 & 0
\end{bmatrix} \lambda = \begin{bmatrix}
\lambda_1 \\
\lambda_2 \\
\lambda_3
\end{bmatrix} \quad \text{(18)} $$

### 2.5 Rotation Matrices

The notation $R^b_a \in SO(3)$ implies that the rotation matrix $R^b_a$ between two frames $a$ and $b$ (from $b$ to $a$) is an element in $SO(3)$, that is the special orthogonal group of order 3:

$$ SO(3) = \{ R_a^b | R_a^b \in \mathbb{R}^{3\times3}, R_a^b \text{ is orthogonal, } \det R_a^b = 1 \} $$

The group $SO(3)$ is a subset of all orthogonal matrices of order 3, i.e. $SO(3) \subset O(3)$ where $O(3)$ is defined as:

$$ O(3) = \{ R_a^b | R_a^b \in \mathbb{R}^{3\times3}, \quad (R_a^b)^T R_a^b = I \} $$

Hence it follows that:

$$ (R_a^b)^{-1} = (R_a^b)^T = R_a^b $$
A principal rotation $\alpha$ about the $i$-axis is denoted as $R_{i,\alpha}$.

The principal rotations (one axis rotations) about the $x, y,$ and $z$-axes are defined as [Fossen, 2002]:

$$R_{x,\phi} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & c\phi & -s\phi \\ 0 & s\phi & c\phi \end{bmatrix}$$

(18)

$$R_{y,\theta} = \begin{bmatrix} c\theta & 0 & s\theta \\ 0 & 1 & 0 \\ -s\theta & 0 & c\theta \end{bmatrix}$$

(19)

$$R_{z,\psi} = \begin{bmatrix} c\psi & -s\psi & 0 \\ s\psi & c\psi & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

(20)

where $s \cdot = \sin(\cdot)$, $c \cdot = \cos(\cdot)$, while $\phi, \theta, \text{ and } \psi$ are the Euler angles.

### 3 Maneuvering and Seakeeping – A Motivating Example

Consider a ship moving in sway (mass-damper) and assume that the other modes can be neglected. This can be mathematically described by considering the motion in one degree of freedom [Faltinsen, 1990], [Newman, 1977]:

$$\ddot{y} = \nu$$

(21)

$$[m + A_{22}(\omega)] \dot{\nu} + B_{22}(\omega) \nu = \tau_{2,FK-diff} + \tau_{2}$$

(22)

where $y$ is the sway position, $\nu$ is the velocity and:

- $m$ = mass
- $A_{22}(\omega)$ = frequency-dependent added mass
- $B_{22}(\omega)$ = frequency-dependent damping
- $\tau_{2,FK-diff}$ = Froude-Krylov and diffraction force in sway
- $\tau_{2}$ = control force in sway
- $\omega$ = frequency of forced oscillation

Notice that the hydrodynamic added mass and damping coefficients, $A_{22}(\omega) = -\dot{Y}_{c}(\omega)$ and $B_{22}(\omega) = -\ddot{Y}_{c}(\omega)$, depend on the frequency of the forced oscillation, see Figure 2. The wave excitation force $\tau_{2,FK-diff}$ is due to wave diffraction whereas the mass and damping forces, $A_{22}(\omega)\dot{\nu}$ and $B_{22}(\omega)\nu$, are caused by the hydrodynamic reaction as a result of the movement of the ship in the water.

The water is assumed to be ideal and thus potential theory can be applied. We will denote frequency-dependent potential damping in sway as $B_{22p}(\omega)$ and frequency-dependent damping due to viscous effects, e.g. skin friction and pressure loads, as $B_{22v}(\omega)$. This suggests that the total frequency-dependent linear damping coefficient is:

$$B_{22}(\omega) = B_{22p}(\omega) + B_{22v}(\omega)$$

(23)

Figure 2: Hydrodynamic added mass $A_{22}(\omega)$ and potential damping $B_{22p}(\omega)$ as a function of frequency $\omega$ for zero velocity $\nu = 0$.

The potential coefficients or hydrodynamic coefficients $A_{22}(\omega)$ and $B_{22}(\omega)$ are usually computed using hydrodynamic software, whereas the viscous part $B_{22v}(\omega)$ is more complicated to determine. Note that $B_{22p}(0) = 0$.

An experimentally motivated model is to assign a nonzero value for $\omega = 0$ which is decaying as $\omega$ increases. In Bailey et al. [1998] a ramp function was used for this purpose. The viscous damper is here modelled as an exponentially decaying function:

$$B_{22v}(\omega) = \beta_{22} e^{-\omega}, \quad \alpha > 0$$

(24)

where $\beta_{22}$ is the zero frequency damping coefficient, that is $B_{22v}(0) = \beta_{22}$. The exponential function has excellent numerical properties and it is straightforward to transform the frequency-dependent model to the time domain.

#### Maneuvering Theory (Low-Frequency Model)

For a ship maneuvering in calm water, $\omega = 0$, the effect due to 1st-order wave loads $\tau_{2,FK-diff}$ is removed from (21)–(22), such that the low-frequency (LF) model becomes:

$$\ddot{y}_{LF} = \nu_{LF}$$

(25)

$$[m - Y_{c}]\dot{\nu}_{LF} - Y_{c}\nu_{LF} = \tau_{2}$$

(26)

where $\nu_{LF}$ and $y_{LF}$ are the LF velocity and position in sway, respectively. The assumption that the 1st-order wave-induced force $\tau_{2,FK-diff}$ is zero is justified in Section 3.1 using linear superposition.
The hydrodynamic (slow motion) derivatives are defined in terms of zero-frequency hydrodynamic coefficients:

\[-Y_v \triangleq A_{22}(0)\]  \hspace{1cm} (27)
\[-Y_\dot{v} \triangleq B_{22}(0) = B_{22c}(0) = \beta_{22}\]  \hspace{1cm} (28)

The hydrodynamic derivatives \(Y_v\) and \(Y_\dot{v}\) are usually computed from experimental data using curve fitting and system identification techniques. The frequency-dependent hydrodynamic coefficients \(A_{22}(\omega)\) and \(B_{22}(\omega)\) can also be computed using hydrodynamic potential theory programs or be determined from a PMM experiment where a scale model of the ship is oscillated at different frequencies \(\omega\) and the resulting hydrodynamic force is measured [Lewis, 1989].

### Seakeeping Theory (Models for Wave Loads)

The drawback with the model (25)–(26) is that only the LF part of the hydrodynamic forces is included in the dynamic model of the ship while the 1st-order wave-frequency (WF) motions \(\tau_{2,FK+diff}\) must be added by assuming linear superposition.

The WF motions can be computed using motion transfer functions which are defined as the response amplitude per unit wave amplitude. This is also referred to as the Response Amplitude Operator (RAO). For our simple model (21)–(22) this corresponds to the ratio between the position amplitude \(y_{WF}\) of the oscillating sway position and the wave amplitude \(\zeta_a\), given by [Journée and Massie, 2001]:

\[\text{RAO}_2(s, \psi_r) = \frac{y_{WF}(s, \psi_r)}{\zeta_a}\]  \hspace{1cm} (29)

where \(\psi_r\) is the wave direction relative to the ship. Hence, for \(s = j\omega\) and:

\[\zeta = \zeta_a \cos(\omega t + \varepsilon)\]  \hspace{1cm} (30)

where \(\varepsilon\) is the wave phase angle, the WF motions in sway become:

\[y_{WF}(t) = \zeta_a \left[\text{RAO}_2(j\omega, \psi_r)\right] \cos(\omega t + \angle\text{RAO}_2(j\omega, \psi_r) + \varepsilon)\]  \hspace{1cm} (31)

Here \(\angle\text{RAO}(j\omega, \psi_r)\) denotes the RAO phase angle. For a typical ship, the RAOs in the \(y\)-direction are shown in Figure 3. The curves were computed using the strip theory program ShipX (VERES) by Marintek [Fathi, 2004].

An alternative method is to compute the 1st-order wave loads \(\tau_{2,FK+diff}\) in (22) directly using the force transfer function (FTF):

\[\text{FTF}_2(s, \psi_r) = \frac{\tau_{2,FK+diff}(s, \psi_r)}{\zeta_a}\]  \hspace{1cm} (32)

such that:

\[\tau_{2,FK+diff}(t) = \zeta_a \left[\text{FTF}_2(j\omega, \psi_r)\right] \cdot \cos(\omega t + \angle\text{FTF}_2(j\omega, \psi_r) + \varepsilon)\]  \hspace{1cm} (33)

### 3.1 Linear Superposition of Low-Frequency (LF) and Wave-Frequency (WF) Models

The models (25)–(26) and (29) can be combined to describe the 1st-order ship-wave interactions \(\tau_{2,FK+diff}\). The principle of linear superposition [Denis and Pierson, 1953] suggests that (Figure 4):

\[y = y_{LF} + y_{WF}\]  \hspace{1cm} (34)

When designing a feedback control system, e.g. an autopilot or a dynamic positioning system, the WF motions are treated as measurement noise that can be added to the LF motions and a disturbance observer (wave filter) is designed to remove the WF from entering the feedback loop, see Figure 5. Moreover, the control system should only compensate for the LF motions in order to reduce wear and tear of the propellers and rudders.
3.2 Frequency-Dependent Model with Wave Loads

The disadvantage with the LF and WF model representations is that hydrodynamic wave loads are represented as zero mean WF motions added to the LF ship motions. This model cannot be used for multi-body operations with interaction forces and it is not possible to monitor the wave-induced forces directly since they are represented as disturbances in position and velocity (motion transfer functions).

From a physical point-of-view, wave loads should be modelled as forces acting on the ship through Newton’s law. This can be done using the frequency-dependent vessel model (22) which is valid for different sea states.

The main problem in doing this is that (22) depends on both the time and the frequency $\omega$. In this model the wave loads are added as an external force and $\tau_{2,FK+\text{diff}}$ is computed from the FTF given by (32), see Figure 7.

For linear systems, the frequency-dependent coefficients $A_{22}(\omega)$ and $B_{22}(\omega)$ in (22) can be transformed to an equivalent time-domain representation thanks to the results of Cummins [1962] and Ogilvie [1964], see Appendix A:

$$[m + A_{22}(\infty)] \ddot{v} + B_{22}(\infty)v + \int_0^t K_{22}(t - \tau)v(\tau)d\tau = \tau_{2,\text{env}} + \tau_2$$  \hspace{1cm} (35)

In (22) only the Froude-Krylov and diffraction excitation force $\tau_{2,FK+\text{diff}}$ (1st-order wave load) was considered. However, in the time-domain other environmental excitation forces like wave drift (2nd-order wave loads), wind and currents can be added directly such that:

$$\tau_{2,\text{env}} = \tau_{2,FK+\text{diff}} + \tau_{2,\text{drift}} + \tau_{2,\text{wind}} + \tau_{2,\text{currents}}$$  \hspace{1cm} (36)

where $\tau_{2,\text{drift}}$ is the wave drift force, $\tau_{2,\text{wind}}$ is the wind force, and $\tau_{2,\text{currents}}$ is the current force. Within the framework of linear wave theory, the 1st-order motions are observed as zero mean oscillations, while 2nd-order terms represent the slowly-varying drift forces.

The integral term (impulse response) in (35) is referred to as the memory effect of the fluid and:

$$A_{22}(\infty) = \lim_{\omega \to \infty} A_{22}(\omega) = \text{constant}$$  \hspace{1cm} (37)

$$B_{22}(\infty) = \lim_{\omega \to \infty} B_{22}(\omega) = \text{constant}$$  \hspace{1cm} (38)

If the ship carries out a harmonic oscillation $y(t) = \cos(\omega t)$, it can easily be shown by combining (22) and (35) that the impulse response function $K_{22}(t)$ in Figure 6 can be computed from one of the following equations [Ogilvie, 1964]:

Figure 5: Linear superposition of maneuvering (low-frequency) model and wave frequency model based on RAOs [Perez and Fossen, 2004].

Figure 6: Typical impulse response function $K_{22}(t)$ as a function of time $t$.

Figure 7: Unified time-domain model for maneuvering and control in a seaway [Perez and Fossen, 2004].
for different environmental forces physical description of the different sea states. Solving (35) the wave-induced forces in the time-domain, giving a more
tures 1 and 8: the motions in 6 DOF [Fossen and Smogeli, 2004], see Fig-
Three orthogonal coordinate systems are used to describe
4.1 Coordinate Systems
The kinematic transformations needed to represent the
the model (35) has the advantage that it represents
uni
calm water, i.e.
and
v
(39)

\[
K_{22}(t) = \frac{2}{\pi} \int_{0}^{\infty} \frac{B_{22}(\omega) - B_{22}(\infty)}{\omega} \cos(\omega t) d\omega
\]

\[
K_{22}(t) = -\frac{2}{\pi} \int_{0}^{\infty} \frac{\omega A_{22}(\omega) - A_{22}(\infty)}{\omega} \sin(\omega t) d\omega
\]

This model (35) has the advantage that it represents
the wave-induced forces in the time-domain, giving a more
physical description of the different sea states. Solving (35)
for different environmental forces \(\tau_{2,env}\) gives responses \(y\) and \(v\) that include the frequency-dependent hydrodynamic
motions. Maneuvering theory, on the contrary, is limited to
calm water, i.e. \(\omega = 0\).

The model (35) represents an important step towards a
unified model for maneuvering and seakeeping. This is ex-
tended to 6 DOF in Section 5.

4 Kinematics
The kinematic transformations needed to represent the
equations of motion in the different coordinate systems are
presented in this section.

4.1 Coordinate Systems
Three orthogonal coordinate systems are used to describe
the motions in 6 DOF [Fossen and Smogeli, 2004], see Fig-
ures 1 and 8:

- **North-East-Down frame (n-frame):** The \(n\)-frame
  \(X_nY_nZ_n\) is assumed fixed on the Earth surface with
  the \(X_n\)-axis pointing North, the \(Y_n\)-axis pointing
  East, and the \(Z_n\)-axis down of the Earth tangent
  plane. The \(n\)-frame position \(p^n = [n, e, d]^{T}\) and
  Euler angles \(\Theta = [\phi, \theta, \psi]^T\) are defined in terms of
  the vector:

  \[
  \eta = [(p^n)^T, \Theta]^T = [n, e, d, \phi, \theta, \psi]^T
  \]

- **Hydrodynamic frame (h-frame):** The hydro-
dynamic forces and moments are defined in a
steadily translating hydrodynamic coordinate system
\(X_hY_hZ_h\) moving along the path of the ship with
the constant speed \(U \geq 0\) with respect to the \(n\)-frame.
The \(X_hY_h\)-plane is parallel to the still water surface,
and the ship carries out oscillations around the mov-
ing frame \(X_hY_hZ_h\). The \(Z_h\)-axis is positive down-
wards, the \(Y_h\)-axis is positive towards starboard,
and the \(X_h\)-axis is positive forwards. This is also referred
to as the equilibrium axis system [Bailey et al., 1998].
The coordinate origin of the \(h\)-frame is denoted \(W\).
The \(h\)-frame generalized position vector is:

  \[
  \xi = [\xi_1, \xi_2, \xi_3, \xi_4, \xi_5, \xi_6]^T
  \]

  where \(\xi_i\) denotes the positions/angles with respect to
  the moving \(b\)-frame.

- **Body-fixed frame (b-frame):** The \(b\)-frame \(X_bY_bZ_b\)
is fixed to the hull, see Figure 1. The coordinate ori-
in is denoted \(O\) and is located on the center line a
distance \(LCO\) relative to \(L_{pp}/2\) (positive backwards)
and a distance \(VCO\) relative to the baseline (positive
upwards). The center of gravity \(G\) with respect to \(O\) is
located at \(r^b_g = [x_g, y_g, z_g]^T\) while the \(h\)-frame origin
\(W\) with respect to \(O\) is located at \(r^b_w = [x_w, y_w, z_w]^T\).
The \(X_b\)-axis is positive toward the bow and the \(X_h\)-axis
is parallel to the mean \(X_b\)-axis, the \(Y_b\)-axis is
positive towards starboard, and the \(Z_b\)-axis is positive
downward. Consequently, the body-fixed \(b\)-frame

  \[
  v^b_o = [u, v, w]^T \text{ in } O \text{ and angular velocities}
  \]
\[ \omega_{bn}^b = [p, q, r]^\top \] with respect to the \( n \)-frame are denoted as:

\[ \nu = [(v_n^b)^\top, (\omega_{bn}^b)^\top]^\top = [u, v, w, p, q, r]^\top \] (41)

The nominal generalized velocity vector is denoted as \( \tilde{\nu} = [U, 0, 0, 0, 0, 0]^\top \). Hence:

\[ \nu = \tilde{\nu} + \delta \nu \] (42)

where \( \delta \nu = [\delta u, \delta v, \delta w, \delta p, \delta q, \delta r]^\top \) is a vector of \( h \)-frame velocities.

### 4.2 Generalized Velocity Transformation

It is convenient to define the vectors without reference to a coordinate frame (coordinate free vector). A vector \( \tilde{v} \) is defined by its magnitude and direction. The vector \( \tilde{v} \) in the point \( O \) decomposed in reference frame \( n \) is denoted as \( v_n^0 \), which is also referred to as a coordinate vector.

The linear velocity \( \tilde{v}_w \) of \( W \) and the angular velocity \( \tilde{\omega}_{hn} \) of the \( h \)-frame with respect to the \( n \)-frame (assumed to be the inertial frame) are:

\[ \tilde{v}_w = \tilde{v}_n + \tilde{\omega}_{hn} \times \tilde{r}_w \] (43)

\[ \tilde{\omega}_{hn} = \tilde{\omega}_{hb} + \tilde{\omega}_{bn} = \tilde{0} \] (44)

where \( \tilde{\omega}_{bn} \) is the average angular velocity of the \( b \)-frame with respect to the \( n \)-frame, and \( \tilde{r}_w \) is the vector from \( O \) to \( W \). Decomposing these vectors into the \( b \)-frame gives:

\[ v_w^b = v_n^b + \omega_{bn}^b \times r_w^b \] (45)

\[ \omega_{bh}^b = -\omega_{hb}^b = \omega_{bn}^b \] (46)

The vector \( \tilde{v}_n \) is defined in terms of the matrix \( S(r_n^0) \in S(3) \) (skew-symmetric matrix of order 3) such that:

\[ \omega_{bn}^b \times r_w^b = -r_w^b \times \omega_{bn}^b = -S(r_w^b)\omega_{bn}^b = S(r_w^b)^\top \omega_{bn}^b \] (47)

where:

\[ S(r_w^b) = -S(r_w^b)^\top = \begin{bmatrix} 0 & -z_w & y_w \\ z_w & 0 & -x_w \\ -y_w & x_w & 0 \end{bmatrix} \] (48)

Define the transformation matrix:

\[ H(r_w^b) \triangleq \begin{bmatrix} I_{3 \times 3} & S(r_w^b)^\top \\ 0_{3 \times 3} & I_{3 \times 3} \end{bmatrix} \] (49)

Then it follows that:

\[ \begin{bmatrix} v_w^b \\ \omega_{bh}^b \end{bmatrix} = H(r_w^b) \begin{bmatrix} v_n^b \\ \omega_{bn}^b \end{bmatrix} \] (50)

### 4.3 Kinematics (b-frame to h-frame)

The transformation from the \( b \)-frame to the \( h \)-frame is done in terms of the small angle rotation matrices:

\[ R_h^b(\Theta) \triangleq R_{h,\xi_4} R_{y,\xi_5} R_{x,\xi_6} \] (51)

where \( \xi_4, \xi_5, \) and \( \xi_6 \) are oscillations of the \( b \)-frame with respect to the \( h \)-frame. These angles are related to \( \phi, \theta, \) and \( \psi \) according to:

\[ \xi_4 = \phi \] (52)

\[ \xi_5 = \theta \] (53)

\[ \xi_6 = \psi - \frac{1}{T} \int_t^{t+T} \psi(\tau) d\tau \] (54)

Hence, \( \xi_6 \) can be understood as the oscillation about the average yaw angle in a given period \( T \) (s).

The principal rotations (small angle assumption) are:

\[ R_{x,\xi_4} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & -\xi_4 \\ 0 & \xi_4 & 1 \end{bmatrix} \] (55)

\[ R_{y,\xi_5} = \begin{bmatrix} 1 & 0 & \xi_5 \\ 0 & 1 & 0 \\ -\xi_5 & 0 & 1 \end{bmatrix} \] (56)

\[ R_{x,\xi_6} = \begin{bmatrix} 1 & -\xi_6 & 0 \\ \xi_6 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \] (57)

Thus \( R_h^b(\Theta^*) \in SO(3) \) becomes:

\[ R_h^b(\Theta^*) = \begin{bmatrix} 1 & -\xi_6 & \xi_5 \\ \xi_6 & 1 & -\xi_4 \\ -\xi_5 & \xi_4 & 1 \end{bmatrix} \] (58)

From (50) it follows that:

\[ \begin{bmatrix} R_h^b(\Theta^*) & 0_{3 \times 3} \\ 0_{3 \times 3} & R_h^b(\Theta^*) \end{bmatrix} \begin{bmatrix} v_w^b \\ \omega_{bh}^b \end{bmatrix} = H(r_w^b) \begin{bmatrix} v_n^b \\ \omega_{bn}^b \end{bmatrix} \]

where \( R_h^b(\Theta^*) = R_h^b(\Theta^*)^{-1} \). Consequently, the velocity transformation between the \( h \) and \( b \) frames becomes:

\[ v_w^h = R_h^b(\Theta^*) \begin{bmatrix} v_n^b + S(r_w^b)^\top \omega_{bn}^b \end{bmatrix} \] (59)

\[ \omega_{bh}^h = R_h^b(\Theta^*) \omega_{bh}^b \] (60)

Since the \( h \)-frame moves along the path of the ship with the
constant speed $U$, (59)–(60) can be expanded as:

$$
\begin{bmatrix}
\dot{\xi}_1 + U \\
\dot{\xi}_2 \\
\dot{\xi}_3 \\
\dot{\xi}_4 \\
\dot{\xi}_5 \\
\dot{\xi}_6
\end{bmatrix}
= R_b^b(\Theta^*) \begin{bmatrix} u \\
v \\
w \\
p \\
q \\
r\end{bmatrix}
+ R_b^b(\Theta^*) S(r_w^b) \begin{bmatrix} p \\
q \\
r \end{bmatrix}
$$

(61)

$$
\begin{bmatrix}
\dot{\xi}_4 \\
\dot{\xi}_5 \\
\dot{\xi}_6
\end{bmatrix}
= T_\Theta(\Theta^*) \begin{bmatrix} p \\
q \\
r \end{bmatrix}
$$

(62)

Note that the total $b$-frame velocity in the horizontal plane is $u = U + \delta u$ and $v = \delta v$ since $\xi_6$ is small, whereas $w = \delta w, p = \delta p, q = \delta q, \text{ and } r = \delta r$.

In the forthcoming we will consider slender ships with starboard/port symmetry implying that DOF 1,3,5 can be decoupled from DOF 2,4,6. Decoupling between the longitudinal and lateral modes, $y_b = y_w = 0$, and neglecting higher-order terms in (61)–(62), i.e. linear theory, gives:

$$
\begin{align*}
\dot{\xi}_1 &= u - U + z_w \delta q = \delta u + z_w \delta q \\
\dot{\xi}_2 &= (U + \delta u) \xi_6 + \delta v + x_w \delta r - z_w \delta p \\
&\approx \delta v + x_w \delta r - z_w \delta p + U \xi_6 \\
\dot{\xi}_3 &= -(U + \delta u) \xi_5 + \delta w - x_w \delta q \\
&\approx \delta w - x_w \delta q - U \xi_5 \\
\dot{\xi}_4 &= \delta p \\
\dot{\xi}_5 &= \delta q \\
\dot{\xi}_6 &= \delta r
\end{align*}
$$

(63)–(68)

Time differentiation of (63)–(68) gives:

$$
\begin{align*}
\ddot{\xi}_1 &= \delta \dot{u} + z_w \delta \dot{q} \\
\ddot{\xi}_2 &= \delta \dot{v} + x_w \delta \dot{r} - z_w \delta \dot{p} + U \delta \dot{r} \\
\ddot{\xi}_3 &= \delta \dot{w} - x_w \delta \dot{q} - U \delta \dot{q} \\
\ddot{\xi}_4 &= \delta \ddot{p} \\
\ddot{\xi}_5 &= \delta \ddot{q} \\
\ddot{\xi}_6 &= \delta \ddot{r}
\end{align*}
$$

(69)–(74)

Let $w_e$ denote the frequency of encounter:

$$
\omega_e = \omega - \frac{U}{g} \omega^2 \cos \psi_r
$$

(75)

where $U$ is the forward speed, $g$ is the acceleration of gravity, and $\psi_r$ is the relative angle of the incident waves. Under the assumption of sinusoidal motions in pitch and yaw, with frequency $\omega_e$ and amplitudes $A_1$ and $A_2$, it follows that:

$$
\begin{align*}
\xi_5 &= A_1 \sin \omega_e t \\
\xi_5 &= A_1 \omega_e \cos \omega_e t \\
\xi_6 &= A_2 \sin \omega_e t \\
\xi_6 &= A_2 \omega_e \cos \omega_e t
\end{align*}
$$

(76)

This implies that:

$$
\xi_6 = -\frac{1}{\omega_e^2} \xi_5, \quad \xi_5 = -\frac{1}{\omega_e^2} \xi_6
$$

(77)

such that the velocity transformations (63)–(68) can be written:

$$
\begin{align*}
\dot{\xi}_1 &= \delta u + z_w \delta q \\
\dot{\xi}_2 &= \delta v + x_w \delta r - z_w \delta p - \frac{U}{\omega_e} \delta \dot{r} \\
\dot{\xi}_3 &= \delta w - x_w \delta q + \frac{U}{\omega_e} \delta \dot{q} \\
\dot{\xi}_4 &= \delta \dot{p} \\
\dot{\xi}_5 &= \delta q \\
\dot{\xi}_6 &= \delta \dot{r}
\end{align*}
$$

(78)–(83)

The velocity (78)–(83) and acceleration (69)–(74) transformations can now be written in compact forms by defining two transformation matrices $J^* \in R^{6 \times 6}$ and $L^* \in R^{6 \times 6}$ according to:

$$
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & -z_w \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\delta \dot{u} \\
\delta \dot{v} \\
\delta \dot{w} \\
\delta \dot{p} \\
\delta \dot{q} \\
\delta \dot{r}
\end{bmatrix}
= J^* (\delta \nu - \frac{U}{\omega_e^2} L^* \delta \dot{\nu})
$$

(84)

$$
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & -z_w \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\delta \dot{u} \\
\delta \dot{v} \\
\delta \dot{w} \\
\delta \dot{p} \\
\delta \dot{q} \\
\delta \dot{r}
\end{bmatrix}
= L^* (\delta \dot{\nu})
$$

(85)

where $\delta \nu = [\delta u, \delta v, \delta w, \delta p, \delta q, \delta r]^T$ and:

$$
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & -1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\ddot{x}_1 \\
\ddot{x}_2 \\
\ddot{x}_3 \\
\ddot{x}_4 \\
\ddot{x}_5 \\
\ddot{x}_6
\end{bmatrix}
= L^* (\delta \nu)
$$

(87)

For station-keeping and low-speed maneuvering, i.e. $U = 0$, we have that $\nu = \delta \nu$. This gives the speed independent transformation [Fossen and Smogeli, 2004]:

$$
\ddot{x} = J^* \nu, \quad \ddot{x} = J^* \nu
$$

(88)

### 4.4 Kinematics (b-frame to n-frame)

The velocity transformation between the $b$ and $n$ frames is:

$$
\begin{bmatrix} v_b^n \\
\end{bmatrix}
= R_b^n(\Theta) \begin{bmatrix} v_b^b \\
\end{bmatrix}
$$

(89)

where the Euler angle rotation matrix (zyx-convention) between the $n$ and $b$ frames is defined as the product of the three principal rotations:

$$
R_b^n(\Theta) \triangleq R_{z, \phi} R_{y, \theta} R_{x, \psi}
$$

(90)
Thus $R^b_\Theta(\Theta) \in SO(3)$ becomes:

$$R^b_\Theta(\Theta) = \begin{bmatrix}
\cos\Theta \sin\Theta - \cos\Theta \sin\Theta \\
\sin\Theta \cos\Theta + \cos\Theta \sin\Theta \\
\cos\Theta \cos\Theta - \sin\Theta \sin\Theta
\end{bmatrix}
$$

The Euler rates satisfy:

$$\dot{\Theta} = T_\Theta(\Theta) \omega^b_{bn}
$$

where $T_\Theta(\Theta) \in \mathbb{R}^{3 \times 3}$ is the Euler angle attitude transformation matrix:

$$T_\Theta(\Theta) = \begin{bmatrix}
1 & \sin\Theta & -\cos\Theta \\
0 & \cos\Theta & \sin\Theta \\
0 & -\sin\Theta & \cos\Theta
\end{bmatrix}, \quad \theta \neq \pm 90^\circ \tag{92}
$$

Consequently:

$$\dot{\eta} = J(\Theta) \nu \tag{94}
$$

where $J(\Theta) \in \mathbb{R}^{6 \times 6}$ is the velocity transformation matrix:

$$J(\Theta) = \begin{bmatrix}
R^b_\Theta(\Theta) & 0_{3 \times 3} \\
0_{3 \times 3} & T_\Theta(\Theta)
\end{bmatrix}, \quad \theta \neq \pm 90^\circ \tag{95}
$$

## 5 Unified Model for Ship Maneuvering and Control in a Seaway

A unified model for maneuvering and seakeeping is attractive for real-time simulation and control design. The presented model is motivated by the results of Bishop and Price [1981] and Bailey et al. [1998]. The 6 DOF ship equations of motion in a seaway should also give new insight into the computational efforts required to implement the equations in a real-time simulator for training purposes and model-based ship control systems.

### 5.1 Frequency Domain Equation

#### Seakeeping Theory (h-frame formulation)

The 6 DOF seakeeping model is usually formulated in the $h$-frame using Newton’s 2nd law:

$$M_{RB} \ddot{\xi} = \delta T_H + \delta T_{FK+diff} + \delta \tau \tag{96}
$$

where $\delta T_{FK+diff}$ is a vector of generalized Froude-Krylov and diffraction forces and $\delta \tau$ is the generalized control forces. The generalized hydrodynamic added mass, damping, and restoring forces are [Faltinsen, 1990]:

$$\delta T_H = -A^*(\omega_c) \dot{\xi} - B^*(\omega_c) \ddot{\xi} - g^*(\xi) \tag{97}
$$

The frequency-dependent hydrodynamic matrices $A^*(\omega_c)$ and $B^*(\omega_c)$ are usually computed using a potential theory program, see Section 7.1. The resulting model is referred to as the frequency domain equation:

$$[M_{RB} + A^*(\omega_c)] \ddot{\xi} + B^*(\omega_c) \dot{\xi} + C^* \dot{\xi} = \delta T_{FK+diff} + \delta \tau \tag{98}
$$

where we have assumed that the restoring forces are linear:

$$g^*(\xi) = C^* \dot{\xi} \tag{99}
$$

This is a good assumption for floating vessels at zero and moderate speeds [Faltinsen, 1990].

#### Seakeeping Theory (b-frame formulation)

In order to derive the $b$-frame seakeeping equations we will make use of the transformations derived in Section 4.3. Recall that the velocity and acceleration in the $b$-frame can be transformed to the $h$-frame by:

$$\dot{\xi} = J^* \dot{\nu} - U^* \dot{\nu} \tag{100}
$$

$$\ddot{\xi} = J^* \ddot{\nu} + U^* \ddot{\nu} \tag{101}
$$

Substituting these expressions into (98) and premultiplication with $J^{*T}$ gives:

$$J^{*T} \left[ M_{RB} + A^*(\omega_c) \right] J^* \dot{\nu} + \left[ C_{RB} + \tilde{C}_A(\omega_c) \right] \delta \nu + \tilde{D}(\omega_c) \delta \nu + g(\xi) = J^{*T} \delta T_{FK+diff} + \delta \tau \tag{102}
$$

where:

$$\tilde{M}_A(\omega_c) = J^{*T} A^*(\omega_c) J^* - \frac{U^*}{\omega_c^2} J^{*T} B^*(\omega_c) L^* \tag{103}
$$

$$\tilde{D}(\omega_c) = J^{*T} B^*(\omega_c) J^* \tag{104}
$$

$$C_{RB} = U J^{*T} M_{RB} L^* \tag{105}
$$

$$\tilde{C}_A(\omega_c) = U J^{*T} A^*(\omega_c) L^* \tag{106}
$$

$$g(\xi) = J^{*T} g^*(\xi) \tag{107}
$$

$$\tau_{FK+diff} = J^{*T} \tau_{FK+diff} \tag{108}
$$

$$\tau - \tilde{\tau} = J^{*T} \tilde{\tau} \tag{109}
$$

where $\tilde{\tau}$ is the steady-state control input needed to obtain $\tau = U$. Note that this transformation generates two new matrices $C_{RB}$ and $\tilde{C}_A(\omega_c)$ which are recognized as the Coriolis and centripetal matrices due to rigid-body
and frequency-dependent added mass, respectively [Fossen, 2002].

For \( x_w = [0, 0, z_w]^T \) we get:

\[
\begin{bmatrix}
0 & 0 & \vdots & 0 \\
0 & m & \vdots & 0 \\
-m & 0 & \ddots & 0 \\
0 & \vdots & \ddots & 0 \\
0 & \vdots & \ddots & 0 \\
\end{bmatrix}
\]

where \( \tilde{N}(\omega_c) \) contains the linear frequency-dependent Coriolis, centripetal, and damping matrices:

\[
\tilde{N}(\omega_c) = \tilde{C}_A(\omega_c) + \tilde{D}(\omega_c)
\]

Thanks to the special structure of \( L^* \), we have:

\[
L^* = L^* J^*
\]

such that:

\[
\tilde{M}_A(\omega_c) = J^* [A^*(\omega_c) - U \omega_c^2 B^*(\omega_c) L^*] J
\]

\[
\tilde{N}(\omega_c) = J^* [B^*(\omega_c) + U A^*(\omega_c) L^*] J^*
\]

### 5.2 Time-Domain Solution

Since (107)–(108) are linear transformations corresponding to transfer functions, the frequency-dependent equation (104) can be transformed to the time-domain using impulse response functions or state-space models [Kristiansen and Egeland, 2003] [Kristiansen, 2005].

The time-domain solution for (104) is (Appendix A):

\[
M_{RB} + \tilde{M}_A(\omega_c) \delta \nu + C_{RB} \delta \nu + \tilde{N}(\omega_c) \delta \nu + \int_{-\infty}^{t} K(t - \tau) \delta \nu(\tau) d\tau + g(\xi) = \tau_{FK+diff} + (\tau - \bar{\tau})
\]

(109)

where \( K(t) \) is a matrix of impulse response functions:

\[
K(t) = \frac{2}{\pi} \int_{0}^{\infty} [\tilde{N}(\omega_c) - \tilde{N}(\infty)] \cos(\omega_c t) d\omega_c
\]

and:

\[
\tilde{M}_A(\infty) = J^* A^*(\infty) J^* \\
\tilde{N}(\infty) = J^* [B^*(\infty) + U A^*(\infty) L^*] J^*
\]

For notational simplicity, we define:

\[
M \triangleq M_{RB} + \tilde{M}_A(\infty) \\
D \triangleq \tilde{N}(\infty)
\]

\[
\mu \triangleq \int_{-\infty}^{t} K(t - \tau) \delta \nu(\tau) d\tau
\]

where \( M \) is the generalized inertia matrix and \( D \) is the linear damping matrix. Hence (109) takes the form:

\[
M \delta \dot{\nu} + C_{RB} \delta \nu + D \delta \nu + \mu + g(\xi) = \tau_{FK+diff} + (\tau - \bar{\tau})
\]

(116)

Substituting the perturbation terms:

\[
\delta \nu = \nu - \tilde{\nu} \quad \Theta^* = \Theta - \Theta_0 \Rightarrow g(\xi) = g(\eta)
\]

into (116) gives:

\[
M \delta \dot{\nu} + C_{RB} \delta \nu + D \delta \nu + \mu + g(\eta) = \tau_{FK+diff} + \tau
\]

(119)

The constant control input \( \bar{\tau} = C_{RB} \bar{\nu} + \bar{D} \bar{\nu} \) corresponding to steady-state \( u = U \), that is \( \delta \dot{\nu} = \delta \nu = 0 \) and \( \tau_{FK+diff} = 0 \), finally gives:

\[
\eta = J(\Theta) \nu
\]

(120)

\[
M \delta \dot{\nu} + C_{RB} \delta \nu + D \delta \nu + \mu + g(\eta) = \tau_{FK+diff} + \tau
\]

(121)

### 5.3 Adding Nonlinear Damping and Environmental Forces in the Time-Domain

The time-domain model (121) can be further extended to include nonlinear damping terms:

\[
\tau_n = -d_n(\Theta, \nu)
\]

(122)

and environmental forces due to wave drift, wind, and currents by writing:

\[
M \dot{\nu} + C_{RB} \nu + D \nu + \mu + d_n(\Theta, \nu) + g(\eta) = \tau_{env} + \tau
\]

(123)

where

\[
\tau_{env} = \tau_{FK+diff} + \tau_{drift} + \tau_{wind} + \tau_{currents}
\]

(124)

The equilibrium \( \delta \dot{\nu} = \delta \nu = 0 \) and \( \tau_{env} = 0 \), corresponding to \( u = U \) and \( v = w = p = q = r = 0 \), is obtained for the control input \( \bar{\tau} = C_{RB} \bar{\nu} + \bar{D} \bar{\nu} + d_n(0, \bar{\nu}) \).
5.3.1 Nonlinear Damping Terms

The nonlinear damping term $\tau_n$ can be found from PMM experiments [Lewis, 1989]. The nonlinear parametrizations used in maneuvering theory are usually classified according to [Clarke, 2003]:

**Truncated Taylor series expansions** [Abkowitz, 1964]. For starboard/port symmetric vessels a vector of 3rd-order terms $\tau_n = [\tau_{n1}, \tau_{n2}, ..., \tau_{n6}]^T$ should be included in addition to linear damping, i.e.:

\[
\tau_{n1} = X_{uuu}u^3 + X_{wuw}u^2w + X_{qqq}q^3 + X_{uwu}uw^2 + X_{uqq}uq^2 + \cdots
\]

\[
\tau_{n2} = Y_{vwv}v^3 + Y_{ppp}p^3 + Y_{rrr}r^3 + Y_{wpp}wp^2 + Y_{vrr}vr^2 + \cdots
\]

\[
\vdots
\]

\[
\tau_{n6} = N_{rrr}r^3 + \cdots
\]

**Second-order modulus models** have been proposed by Fedyaevsky and Sobolev [1963], Norrbom [1970], and Blanke and Christensen [1993] for instance. For the lateral motions $\tau_n = [\tau_{n2}, \tau_{n4}, \tau_{n6}]^T$, Blanke and Christensen [1993] give the following second-order modulus model:

\[
\tau_{n2} = Y_{uvu}u v + Y_{ur}ur + Y_{v|v|v}v r + Y_{u|v|r}v r + Y_{uvu}u v + Y_{uvu}u v
\]

\[
\tau_{n4} = K_{uvu}u v + K_{ur}ur + K_{v|v|v}v r + K_{u|v|r}v r + K_{uvu}u v + K_{uvu}u v
\]

\[
\tau_{n6} = N_{uvu}u v + N_{uvu}u v + N_{u|v|r}u r + N_{r|v|r}r r + N_{v|v|r}v r + N_{u|v|r}u r + N_{u|v|r}u r
\]

Several other models are available in the literature; see Fossen [1994, 2002], Bertram [2004], and Perez [2005] and references therein.

6 State-Space representation for the Unified Model

This section presents state-space models for forward simulation of the unified model in Section 5. The cases for forward and zero speed are treated separately.

6.1 Forward Speed State-Space Representation

Consider the unified model (123):

\[
\dot{\mathbf{M}}\mathbf{v} + C_{RB}\mathbf{v} + D\mathbf{v} + \mathbf{u} + d_n(\Theta, \mathbf{v}) + g(\eta) = \tau_{env} + \tau
\]

where:

\[
\mathbf{u} = \int_{t-\tau}^{t} \mathbf{K}(t-\tau)\delta \mathbf{v}(\tau) d\tau
\]

\[
\mathbf{K}(t) = \frac{2}{\pi} \int_{-\infty}^{\infty} \tilde{\mathbf{N}}(\omega_c) - \tilde{\mathbf{N}}(\infty) \cos(\omega_c t) d\omega_c
\]

For causal systems:

\[
\mathbf{K}(t) = 0 \text{ for } t < 0
\]

such that:

\[
\mathbf{u}(t) = \int_{t-\tau}^{t} \mathbf{K}(t-\tau)\delta \mathbf{v}(\tau) d\tau \text{ causal}
\]

\[
\mathbf{K}(t) = \int_{t-\tau}^{t} \mathbf{K}(t-\tau)\delta \mathbf{v}(\tau) d\tau
\]

where $\mathbf{K}(t-\tau)$ is the retardation function.

Kristiansen and Engeland [2003] and Kristiansen [2005] have developed a state-space formulation for $\mathbf{u}$. If $\delta \mathbf{v}$ is a unit impulse, then $\mathbf{u}$ given by (129) will be an impulse response function. Consequently, $\mathbf{u}$ can be approximated by a linear reduced-order state-space model:

\[
\dot{\mathbf{x}} = \mathbf{A}_r \mathbf{x} + \mathbf{B}_r \delta \mathbf{v}, \quad \mathbf{x}(0) = 0
\]

\[
\mathbf{u} = \mathbf{C}_r \mathbf{x} + \mathbf{D}_r \delta \mathbf{v}
\]

where $(\mathbf{A}_r, \mathbf{B}_r, \mathbf{C}_r, \mathbf{D}_r)$ are constant matrices of appropriate dimensions and $\delta \mathbf{v} = \mathbf{v} - \bar{\mathbf{v}}$. Applying the Laplace transformation to (130)–(131), the damping term (129) can be written as:

\[
\mathbf{u}(s) = \mathbf{D}_{\text{mem}}(s) \delta \mathbf{v}(s)
\]

where $\mathbf{D}_{\text{mem}}(s)$ is a transfer function matrix. Notice that the filter:

\[
\mathbf{D}_{\text{mem}}(s) = \mathbf{C}_r(s\mathbf{I} - \mathbf{A}_r)^{-1} \mathbf{B}_r + \mathbf{D}_r
\]

now contains the memory effect of the fluid. The resulting nonlinear state-space model is:

\[
\dot{\mathbf{y}} = \mathbf{J}(\Theta)\mathbf{v}
\]

\[
\mathbf{M}\ddot{\mathbf{v}} + C_{RB}\mathbf{v} + D\mathbf{v} + d_n(\Theta, \mathbf{v}) + g(\eta) = \tau_{env} + \tau
\]

\[
\dot{\mathbf{x}} = \mathbf{A}_r \mathbf{x} + \mathbf{B}_r \delta \mathbf{v}, \quad \mathbf{x}(0) = 0
\]

\[
\mathbf{u} = \mathbf{C}_r \mathbf{x} + \mathbf{D}_r \delta \mathbf{v}
\]

Notice that the property:

\[
\mathbf{M} = \mathbf{M}^T > 0, \quad \dot{\mathbf{M}} = 0
\]
holds for this model since the generalized added mass matrix $\tilde{M}_A(\infty)$ is frequency independent and symmetric. Hence, Lyapunov-based control methods [Fossen, 2002] can utilize the standard kinetic energy formulation:

$$V(\nu) = \frac{1}{2} \nu^T M \nu > 0, \quad \forall \nu \neq 0$$  \hspace{1cm} (139)

6.2 Zero-Speed State-Space Representation

An attractive simplification of (134)–(137) is the DP representation which is obtained for $U = 0$ and $\omega_c = \omega$. Hence, $C_{RB} \nu = 0, \tilde{C}_A(\omega) \nu = 0, d(\Theta, \nu)$ is small, and $g(\eta) \approx G\eta$, such that [Fossen and Smogeli, 2004]:

$$M \ddot{\nu} + D \nu + \int_0^t K(t-\tau)\nu(\tau)d\tau + G\eta = \tau_{env} + \tau$$  \hspace{1cm} (140)

where:

$$K(t) = \frac{2}{\pi} \int_0^\infty J^* (B(\omega) - B(\infty)) J^* \cos(\omega t)d\omega$$

$$M = M_{RB} + J^* A(\infty) J^*$$

$$D = J^* B(\infty) J^*$$

The state-space model now becomes:

$$\dot{\eta} = J(\Theta) \nu$$  \hspace{1cm} (141)

$$M \dot{\nu} + D \nu + \mu + G\eta = \tau_{env} + \tau$$  \hspace{1cm} (142)

$$\dot{\chi} = A_r \chi + B_r \nu$$  \hspace{1cm} (143)

$$\mu = C_r \chi + D_r \nu$$  \hspace{1cm} (144)

where $\chi(0) = 0$.

7 Strip Theory

This section presents a method for transformation of the STF hydrodynamic coefficients [Salvesen et al., 1970] used in the unified model of Section 5.

7.1 Background

In 1949 Ursell published his famous paper on potential theory for determining the hydrodynamic coefficients of semicircular cross sections, oscillating in deep water in the frequency domain [Ursell, 1949]. This was used as a rough estimation for zero speed ship applications. Motivated by this Grim [1953], Tasai [1959, 1960, 1961], Gerritsma [1960] and others used conformal mapping techniques like the Lewis conformal mapping to transform ship-like cross sections to semicircles such that more realistic hull forms could be calculated. Exciting wave loads were computed using undisturbed regular waves. Denis and Pierson [1953] published a superposition method to describe the irregular waves assuming that the sea could be described as a sum of many simple harmonic waves; each wave with its own frequency, amplitude, direction and random phase lag. The responses of the ship at zero speed were calculated for each of these individual harmonic waves and superimposed.

The extension to forward speed was made available by Korvin-Kroukovsky and Jacobs [1957], and was further improved in the 60s. Later, Frank [1967] published a pulsating source theory to calculate the hydrodynamic coefficients of a cross section of a ship in deep water directly, without using conformal mapping. Keil [1974] published a theory for obtaining the potential coefficients in very shallow water using Lewis conformal mappings. The STF strip theory [Salvesen et al., 1970], which accounts for forward speed as well as transom stern effects, is made available through the program ShipX (VERES) [Fathi and Hoff, 2004].

Since strip theory determines the hydrodynamic coefficients from potential theory, it is common to calculate the added resistance of a ship due to waves e.g. by using the integrated pressure method by Boese [1970] or the radiated energy method [Gerritsma and Beukelman, 1972]. In roll it is common to use the viscous correction by Ikeda et al. [1978] based on semi-empirical methods.

For zero-speed, 3-D potential theory can be used to compute the hydrodynamic coefficients [WAMIT, 2004], while the panel-method program TMIT [Korsmeyer et al., 1999] computes the impulse-response functions for different forward speeds. However, the 2-D approach (strip theory) is still very favorable for calculating the behavior of a ship at forward speed. For a more detailed discussion on advantages and disadvantages when comparing 2-D with 3-D theories; see Faltinsen and Svensen [1990].

7.2 Transformation of STF Coefficients

The STF strip theory coefficients of Salvesen et al. [1970] listed in Tables 3 and 4 in Appendix B should be transformed from the $b$-frame to the $h$-frame in order to implement the state-space model (134)–(137). This also removes the representation singularity at $\omega_c = 0$ caused by terms like $U/\omega_c^2$ and $U^2/\omega_c^2$.

Consider the $b$-frame frequency-dependent matrices:

$$\tilde{M}_A(\omega_c) = (\tilde{J}^* \tilde{J})^{-1} \left[ A(\omega_c) - \frac{U}{\omega_c^2} B(\omega_c) L^* \right] J^*$$  \hspace{1cm} (145)

$$\tilde{N}(\omega_c) = (\tilde{J}^* \tilde{J})^{-1} \left[ B(\omega_c) + U A(\omega_c) L^* \right] J^*$$  \hspace{1cm} (146)

Let the terms within the brackets be denoted as:

$$X(\omega_c) = A(\omega_c) - \frac{U}{\omega_c^2} B(\omega_c) L^*$$  \hspace{1cm} (147)

$$Y(\omega_c) = B(\omega_c) + U A(\omega_c) L^*$$  \hspace{1cm} (148)
such that:
\[
\tilde{M}_A(\omega_c) = J^*X(\omega_c)J^* \quad (149)
\]
\[
Y(\omega_c) = J^*Y(\omega_c)J^* \quad (150)
\]

Let us now consider the \(B_{55}\) coefficient in Table 3:
\[
B_{55} = B_{55}^0 + \frac{U^2}{\omega_c^2}B_{33}^0 + Ux_A^2a_{33}^A + \frac{U^2}{\omega_c^2}x_Ab_{33}^A \quad (151)
\]
which clearly is undefined for \(\omega_c = 0\). However, the coefficient \(\tilde{N}_{55}(\omega_c)\) with \(J^* = I\) is well conditioned since:
\[
\tilde{N}_{55} = B_{55} - UA_{53} = B_{55}^0 + \frac{U^2}{\omega_c^2}B_{33}^0 + Ux_A^2a_{33}^A - \frac{U^2}{\omega_c^2}x_Ab_{33}^A
\]
\[-U\left(-A_{33}^o + \frac{U}{\omega_c}B_{33}^0 - \frac{U}{\omega_c}x_Ab_{33}^A\right)
\] = \[B_{53}^0 + UA_{53}^o + Ux_A^2a_{33}^A\quad (152)
\]
This also holds for the other coefficients. Inspired by this, a systematic transformation procedure is presented below.

### 7.3 Longitudinal and Lateral Transformations

The transformation matrix \(J^*\) given by (86) can be partitioned according to:
\[
J_1^* = \begin{bmatrix}
1 & 0 & z_w \\
0 & 1 & -x_w \\
0 & 0 & 1
\end{bmatrix} \quad (153)
\]
\[
J_2^* = \begin{bmatrix}
1 & -z_w & x_w \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix} \quad (154)
\]
for the longitudinal and lateral modes, respectively. At the infinity frequency we have that:
\[
\tilde{M}_A(\infty) = J^*A(\infty)J^* \\
\tilde{N}(\infty) = J^*[B(\infty) + UA(\infty)L^*]J^*
\]
which both are constant matrices. The \(Y(\omega_c)\) matrix is:
\[
Y(\omega_c) = B(\omega_c) + UA(\omega_c)L^*
\]
Substituting the STF coefficients from Table 3 into the expression for \(Y(\omega_c)\) gives the following longitudinal transformation:
\[
\begin{bmatrix}
Y_{11} & Y_{13} & Y_{15} \\
Y_{31} & Y_{33} & Y_{35} \\
Y_{51} & Y_{53} & Y_{55}
\end{bmatrix} = U \begin{bmatrix}
0 & 0 & 0 \\
0 & a_{33}^A & -x_Aa_{33}^A \\
0 & -x_Aa_{33}^A & x_A^2a_{33}^A
\end{bmatrix}
+ \begin{bmatrix}
0 & 0 & 0 \\
0 & B_{33} & B_{35} \\
0 & B_{33} + UA_{33}^0 & B_{55} + UA_{53}^0
\end{bmatrix}
\]
and
\[
\begin{bmatrix}
\tilde{N}_{11} & \tilde{N}_{13} & \tilde{N}_{15} \\
\tilde{N}_{31} & \tilde{N}_{33} & \tilde{N}_{35} \\
\tilde{N}_{51} & \tilde{N}_{53} & \tilde{N}_{55}
\end{bmatrix} = J_1^* \begin{bmatrix}
Y_{11} & Y_{13} & Y_{15} \\
Y_{31} & Y_{33} & Y_{35} \\
Y_{51} & Y_{53} & Y_{55}
\end{bmatrix} J_1^*
\]
\[
\begin{bmatrix}
Y_{22} & Y_{24} & Y_{26} \\
Y_{42} & Y_{44} & Y_{46} \\
Y_{62} & Y_{64} & Y_{66}
\end{bmatrix} = U \begin{bmatrix}
a_{23}^A & a_{24}^A & x_Aa_{22}^A \\
a_{23}^A & a_{24}^A & x_Aa_{22}^A \\
x_Aa_{23}^A & x_Aa_{24}^A & x_A^2a_{22}^A
\end{bmatrix}
+ \begin{bmatrix}
B_{22}^0 & B_{24}^0 & B_{26}^0 \\
B_{42}^0 & B_{44}^0 & B_{46}^0 \\
B_{62}^0 - UA_{22}^0 & B_{64}^0 - UA_{24}^0 & B_{66}^0 - UA_{22}^0
\end{bmatrix}
\]
\[
\begin{bmatrix}
\tilde{N}_{22} & \tilde{N}_{24} & \tilde{N}_{26} \\
\tilde{N}_{42} & \tilde{N}_{44} & \tilde{N}_{46} \\
\tilde{N}_{62} & \tilde{N}_{64} & \tilde{N}_{66}
\end{bmatrix} = J_2^* \begin{bmatrix}
Y_{22} & Y_{24} & Y_{26} \\
Y_{42} & Y_{44} & Y_{46} \\
Y_{62} & Y_{64} & Y_{66}
\end{bmatrix} J_2^*
\]
(155)

Notice that all singular points due to the terms \(U/\omega_c^2\) and \(U^2/\omega_c^2\) now have been removed. Also notice that the \(Y\) matrix can be represented as a symmetric matrix due to zeros speed terms \(B_{33}^0\) and tail effects \(a_{ij}^o\), and a skew-symmetric matrix due to the \(A_{ij}^o\) terms.

### 8 Relationship between Maneuvering and Seakeeping Theory

In Section 5 the unified model was derived in the \(b\)-frame using seakeeping theory and nonlinear damping terms. This is highly advantageous since the resulting model incorporates the maneuvering equations as a special case.

The unified model is related to classical maneuvering theory by neglecting the memory effect of the fluid i.e. only considering the static terms corresponding to the zero frequency. This is illustrated below.
Figure 9: Maneuvering of a tanker in calm weather. For this case \( \omega_c = 0 \) is a good approximation.

### 8.1 LF and WF Models

In maneuvering theory the low-frequency assumption:

\[
\omega_c = 0
\]

implies that the motions can be separated into LF and WF motion components. The zero-frequency model is:

\[
\dot{\eta}_{LF} = J(\Theta_{LF})\nu_{LF}
\]

(158)

\[
[M_{RB} + M_A] \dot{\eta}_{LF} + C_{RB}\nu_{LF} + N\nu_{LF} + d_u(\Theta_{LF}, \nu_{LF}) + g(\eta_{LF}) = \tau_{env} + \tau
\]

(159)

where the oscillatory derivatives \( \tilde{M}_A(\omega_c) \) and \( \tilde{N}(\omega_c) \) are evaluated at \( \omega_c = 0 \), that is:

\[
M_A = \tilde{M}_A(0)
\]

(160)

\[
N = \tilde{N}(0)
\]

(161)

Note that \( \tau_{env} \) for \( \tau_{FK+dif} = 0 \) reduces to:

\[
\tau_{env} = \tau_{drift} + \tau_{wind} + \tau_{currents}
\]

(162)

This is done under the assumption that the WF motions due to \( \tau_{FK+dif} \) can be added directly to the output as two signals \( \eta_{WF} \) and \( \nu_{WF} \), that is:

\[
\eta = \eta_{LF} + \eta_{WF}
\]

(163)

\[
\nu = \nu_{LF} + \nu_{WF}
\]

(164)

Figure 9 shows a ship maneuvering in calm weather where \( \omega_c = 0 \) is a good assumption. In Figure 10 this assumption is clearly violated, suggesting that the unified model in Section 5 should be applied instead.

The hydrodynamic derivatives are defined in terms of the matrices \( M_A \) and \( N \) according to (see Section 5.1):

\[
M_A = J^* A(0) J - \lim_{\omega_c \to 0} U \omega_c J^* B(\omega_c) L^*
\]

\[
N = J^* [B(0) + U A(0) L^*] J
\]

8.2 Decoupled Maneuvering Equations

The linear longitudinal maneuvering equations corresponding to (159) takes the following form (assuming that \( g(\eta_{LF}) = G\eta_{LF} \) and \( d_u = 0 \)):

\[
\begin{bmatrix}
X_u & X_v & X_w & X_p & X_q & X_r \\
Y_u & Y_v & Y_w & Y_p & Y_q & Y_r \\
Z_u & Z_v & Z_w & Z_p & Z_q & Z_r \\
K_u & K_v & K_w & K_p & K_q & K_r \\
M_u & M_v & M_w & M_p & M_q & M_r \\
N_u & N_v & N_w & N_p & N_q & N_r
\end{bmatrix}
\]

\[
\begin{bmatrix}
\dot{\eta}_{LF} \\
\dot{\nu}_{LF} \\
\dot{\eta}_{env} \\
\dot{\nu}_{env} \\
\dot{\theta}_{LF} \\
\dot{\omega}_{LF}
\end{bmatrix}
\]

\[
= -
\begin{bmatrix}
X_u & X_v & X_w & X_p & X_q & X_r \\
Y_u & Y_v & Y_w & Y_p & Y_q & Y_r \\
Z_u & Z_v & Z_w & Z_p & Z_q & Z_r \\
K_u & K_v & K_w & K_p & K_q & K_r \\
M_u & M_v & M_w & M_p & M_q & M_r \\
N_u & N_v & N_w & N_p & N_q & N_r
\end{bmatrix}
\begin{bmatrix}
\dot{\eta}_{LF} \\
\dot{\nu}_{LF} \\
\dot{\eta}_{env} \\
\dot{\nu}_{env} \\
\dot{\theta}_{LF} \\
\dot{\omega}_{LF}
\end{bmatrix}
\]

\[
= -
\begin{bmatrix}
X_u & X_v & X_w & X_p & X_q & X_r \\
Y_u & Y_v & Y_w & Y_p & Y_q & Y_r \\
Z_u & Z_v & Z_w & Z_p & Z_q & Z_r \\
K_u & K_v & K_w & K_p & K_q & K_r \\
M_u & M_v & M_w & M_p & M_q & M_r \\
N_u & N_v & N_w & N_p & N_q & N_r
\end{bmatrix}
\begin{bmatrix}
\dot{\eta}_{LF} \\
\dot{\nu}_{LF} \\
\dot{\eta}_{env} \\
\dot{\nu}_{env} \\
\dot{\theta}_{LF} \\
\dot{\omega}_{LF}
\end{bmatrix}
\]
The lateral maneuvering equations takes the form:

\[
\begin{bmatrix}
 m & 0 & 0 \\
 0 & I_{zz} - I_{xx} & 0 \\
 0 & -I_{zz} & I_{xx}
\end{bmatrix}
\begin{bmatrix}
 \dot{v}_{LF} \\
 \dot{p}_{LF} \\
 \dot{r}_{LF}
\end{bmatrix}
+\begin{bmatrix}
 0 & 0 & mU \\
 0 & 0 & 0 \\
 0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
 v_{LF} \\
 p_{LF} \\
 r_{LF}
\end{bmatrix}
-\begin{bmatrix}
 Y_0 & Y_p & Y_r \\
 K_0 & K_p & K_r \\
 N_0 & N_p & N_r
\end{bmatrix}
\begin{bmatrix}
 \dot{v}_{LF} \\
 \dot{p}_{LF} \\
 \dot{r}_{LF}
\end{bmatrix}
-\begin{bmatrix}
 Y_0 & Y_p & Y_r \\
 K_0 & K_p & K_r \\
 N_0 & N_p & N_r
\end{bmatrix}
\begin{bmatrix}
 v_{LF} \\
 p_{LF} \\
 r_{LF}
\end{bmatrix}
-\begin{bmatrix}
 0 & 0 & 0 \\
 0 & K_0 & 0 \\
 0 & 0 & \psi_{LF}
\end{bmatrix}
\begin{bmatrix}
 \tau_2,env \\
 \tau_4,env \\
 \tau_6,env
\end{bmatrix}
=\begin{bmatrix}
 \tau_2 \\
 \tau_4 \\
 \tau_6
\end{bmatrix}
\]

9 The History of Model-Based Ship Control

This section briefly describes the history of the gyroscope and how it contributed to the development of the first automatic ship steering mechanism in 1911 to the fully automated systems of today based on gyro compasses and global satellite navigation systems.

9.1 The Gyroscope and its Contributions to Ship Control

In 1851 Léon Foucault, a French physicist, demonstrated the Earth’s rotation by showing that a pendulum continued to swing in the same plane while the Earth turned around. This inspired him to invent the gyroscope the next year. He named the device from the Greek words gyro, “revolution,” and skopein, “to view” because he used it to “view the Earth’s rotation.”

However, the first recorded construction of the gyroscope is usually credited to Bohnenberger in 1810 who used a heavy ball instead of a wheel. Unfortunately, this faded into history since it had no scientific application. 80 years later Hopkins demonstrated the first electrically driven gyroscope. The development of the electrically driven gyroscope was motivated by the need of more reliable navigation systems for steel ships and underwater warfare (magnetic compasses are sensitive for magnetic disturbances), [see Allensworth, 1999; Bennet, 1979].

In parallel works, Anschütz and Sperry both worked on a practical application of the gyroscope. In 1908 Anschütz patented the first North seeking gyrocompass while Sperry was granted a patent for his ballistic compass in 1911.

9.2 Model-Based Ship Control

The invention of gyroscopes was one of the breakthroughs in automatic ship control since it gave reliable heading measurements $\psi$. The gyro together with linear accelerometers are also the key components of a vertical reference unit (VRU) which measures the roll and pitch angles $(\phi, \theta)$. Today, global satellite navigation systems have further extended the possibilities for automatic control and terrestrial navigation of ships since they provide the user with the North-East-Down positions $(n, e, d)$.

A marine vessel control system is usually constructed as three independent blocks denoted as the guidance, navigation and control (GNC) systems. These systems interact with each other through data and signal transmission as illustrated in Figure 11 where a conventional ship autopilot is shown.

GNC, in its most basic form, is a reference model...
(guidance system), a sensor system (navigation system) and a feedback control system. In its most advanced form, the GNC blocks represent three interconnected subsystems [Fossen, 2002]:

**Guidance** is the action or the system that continuously computes the reference (desired) position, velocity and acceleration of a vessel to be used by the control system. These data are usually provided to the human operator and the navigation system. The basic components of a guidance system are motion sensors, external data like weather data (wind speed and direction, wave height and slope, current speed and direction, etc.) and a computer. The computer collects and processes the information, and then feeds the results to the vessel’s control system. In many cases, advanced optimization techniques are used to compute the optimal trajectory or path for the vessel to follow. This might include sophisticated features like fuel optimization, minimum time navigation, weather routing, collision avoidance, formation control and schedule meetings.

**Navigation** is the science of directing a craft by determining its position, course, and distance traveled. In some cases velocity and acceleration are determined as well. This is usually done by using a satellite navigation system combined with motion sensors like accelerometers and gyroscopes. The most advanced navigation system for marine applications is the *inertial navigation system* (INS). Navigation is derived from the Latin *navis*, “ship,” and *agere*, “to drive.” It originally denoted the art of ship driving, including steering and setting the sails. The skill is even more ancient than the word itself, and it has evolved over the course of many centuries into a technological science that encompasses the planning and execution of safe, timely, and economical operation of ships, underwater vehicles, aircraft, and spacecraft.

**Control** is the action of determining the necessary control forces and moments to be provided by the vessel in order to satisfy a certain control objective. The desired control objective is usually seen in conjunction with the guidance system. Examples of control objectives are minimum energy, set-point regulation, trajectory tracking, path following, maneuvering etc. Constructing the control algorithm involves the design of feedback and feedforward control laws. The outputs from the navigation system, position, velocity and acceleration, are used for feedback control while feedforward control is implemented using signals available in the guidance system and other external sensors.

In the forthcoming sections, we will focus on the:

- Classical 1 DOF autopilot design for heading (yaw) control
- Extensions to 3 DOF (surge, sway, and yaw) maneuvering and station-keeping (dynamic positioning)

The modeling techniques presented in this paper can also be extended to rudder-roll damping and fin stabilization using models in 4 DOF (surge, sway, roll, and yaw) [Perez, 2005] as well as the general motion in 6 DOF.

### 9.3 Process Plant and Control Plant Models

When designing model-based ship control systems it is important to distinguish between the control plant and process plant models. The following definitions are adopted from Sørensen [2005]:

**Control Plant Model** is a simplified mathematical description containing only the main physical properties of the process or plant. This model may constitute a part of the controller. The control plant model is also used in analytical stability analysis using e.g. eigenvalues, Lyapunov stability, or passivity.

**Process Plant Model** is a comprehensive description of the actual process and it should be as detailed as needed. The main purpose of this model is to simulate the real plant dynamics. The process plant model is used in numerical performance and robustness analyses, and testing of the control systems.

### 10 Heading Autopilot Systems

In this section, we describe the models for autopilot design and the construction of conventional model-based autopilot systems.

#### 10.1 Classical Autopilot (LF Model)

The most common model used in heading autopilot systems is the well celebrated Nomoto model [Nomoto et al., 1957], which can be derived from the maneuvering model:

$$
\dot{\psi}_{LF} = r_{LF} (165)
$$

$$(I_z - N_r)\dot{r}_{LF} - N_r \tau_{LF} = \tau_N (166)$$

where $-N_z > 0$ and $-N_r > 0$ are the hydrodynamic derivatives, $r_{LF}$ and $\psi_{LF}$ are the LF yaw rate and yaw angle, $\tau_{wind}$ is the wind moment, and $\tau_{rudder}$ is the control input (yaw moment).

If wind speed and direction are measured, $\tau_{wind}$ can be estimated using wind coefficient tables.
Then the rudder command is computed from the feedback signal \(\tau_N\) and the feedforward signal \(\tau_{\text{wind}}\) as:

\[
\tau_{\text{rudder}} = \tau_N - \tau_{\text{wind}}
\]  

(167)

The Nomoto time constant \(T\) and gain constant \(K\) for this model can be defined as:

\[
T \triangleq \frac{I_z - \dot{N}_r}{-N_r}, \quad K \triangleq \frac{1}{-N_r}
\]  

(168)

This gives:

\[
\dot{\psi}_{LF} = r_{LF}
\]  

(169)

\[
T\dot{r}_{LF} + r_{LF} = K\tau_N
\]  

(170)

\[
\dot{\psi} = \dot{\psi}_{LF} + \dot{\psi}_{WF}
\]  

(171)

where motion due to 1st-order wave loads are added directly to the output.

The wave-induced motions \(\dot{\psi}_{WF}\) are computed using the RAO transfer function:

\[
\text{RAO}(s, \psi_r) = \frac{\psi_{WF}(s, \psi_r)}{\zeta_a}
\]  

(172)

For certain ships like large tankers it is necessary to add a nonlinear maneuvering characteristic. Again a zero-frequency assumption is used. A frequently used nonlinear model is [Norrbin, 1963]:

\[
T\dot{r}_{LF} + r_{LF} + \alpha r^3_{LF} = K\tau_N
\]  

(173)

where \(\alpha > 0\) describes the nonlinear maneuvering characteristic.

### 10.2 Frequency-Dependent Autopilot Model

The frequency-dependent model (seakeeping theory) is:

\[
[I_z + \dot{M}_{A66}(\omega_e)]\ddot{r} + \dot{N}_{66}(\omega_e)r = \tau_N
\]  

(174)

which relates to maneuvering theory \((\omega_e = 0)\) according to:

\[
-N_r \triangleq \dot{M}_{A66}(0)
\]  

(175)

\[
-N_r \triangleq \dot{N}_{66}(0)
\]  

(176)

The unified model takes the form:

\[
\dot{\psi} = r
\]  

(177)

\[
[I_z + \dot{M}_{A66}(\infty)]\ddot{r} + \dot{N}_{66}(\infty)r
\]  

\[
+ \int_0^t K_{66}(t - \tau)r(\tau)d\tau + \alpha r^3 = \tau_{\text{env}} + \tau_N
\]  

(178)

where the disturbance \(\tau_{\text{env}}\) represents wave loads due to Froude-Krylov forces, diffraction forces, and wave drift etc. Notice that we have added the nonlinear damper \(\alpha r^3\) directly to the time-domain equation (178). We have now extended the classical autopilot model (173) to describe different sea-states.

The integral term in (178) can be numerically computed e.g. by using trapezoidal integration. An alternative approach could be to approximate the impulse response:

\[
\mu = \int_0^t K_{66}(t - \tau)r(\tau)d\tau
\]  

(179)

by a state-space model \((A_r, b_r, c_r, d_r)\) [Kristiansen and Egeland, 2003]. Hence, we can write the unified autopilot model in state-space form as:

\[
\dot{\psi} = r
\]  

(180)

\[
[I_z + \dot{M}_{A66}(\infty)]\ddot{r} + \dot{N}_{66}(\infty)r + \mu + \alpha r^3 = \tau_{\text{env}} + \tau_N
\]  

(181)
\[ \dot{\chi} = A_r \chi + b_r r, \quad \chi(0) = 0 \]  
\[ \mu = c_r^T \chi + d_r r \]  
(182)  
(183)

The state-space model (182)–(183) will typically be of order 5 in order to approximate the impulse response (179) accurately. Hence, the autopilot model including the fluid memory effect is compactly represented as \( 2 + 5 = 7 \) ODEs. The advantage of the model representation (180)–(183) to (169)–(171) is that it incorporates the memory effect of the fluid for varying sea states.

### 10.3 Autopilot Design

The autopilot systems of Sperry and Minorsky were both single-input single-output (SISO) control systems where the heading (yaw angle) of the ship was measured by a gyro compass. Today, this signal is fed back to a computer in which a PID-control system (autopilot) is implemented in software. The autopilot compares the operator set-point (desired heading) with the measured heading and computes the rudder command, which is then transmitted to the rudder servo for corrective action.

The main difference between the autopilot systems of Sperry and Minorsky and the modern autopilot is the increased functionality that has been added with sophisticated features like [Fossen, 2002]:

- Wave filtering; avoids 1st-order wave disturbances being fed back to the actuators.
- Adaptation to varying environmental conditions, shallow water effects and time-varying model parameters, e.g. changes in mass and centre of gravity.
- Wind feedforward for accurate and rapid course-changing maneuvers.
- Reference feedforward using a dynamic model, \( \dot{\psi}_d, \dot{r}_d, \) and \( \ddot{r}_d, \) for course changing maneuvers. Course-keeping is obtained by using a constant reference signal, \( \psi_d = \text{constant}, \) as input to the reference model.

We will discuss some of these features more closely in the next sub-section.

#### 10.3.1 Conventional Autopilot Design (Maneuvering Model)

Assume that both \( \psi \) and \( r \) are measured by a compass and a rate gyro. A full state feedback PID-controller \( \tau_N \) for (169)–(171) can then be designed as [Fossen, 2002]:

\[
\tau_N = \tau_{FF} = \frac{1}{K} \left[ K_p \ddot{\psi} + K_d \dot{\psi}_d + K_i \int_0^t \dot{\psi}(\tau) d\tau \right] + \tau_{mem} \]

(184)

where \( \tau_N \) is the controller yaw moment, \( \tau_{FF} \) is a feedforward term to be determined, and

\[
\dot{\psi} = \psi_{LF} - \psi_d \quad (185)
\]
\[
\ddot{r} = r_{LF} - r_d \quad (186)
\]

represent the yaw angle and yaw rate tracking errors for the reference signals \( \psi_d \) and \( r_d. \) The controller gains are:

\[
K_p > 0 \quad \text{proportional gain constant}
\]
\[
T_d > 0 \quad \text{derivative time constant}
\]
\[
T_i > 0 \quad \text{integral time constant}
\]

The controller gains can be found by pole placement, e.g. [Fossen 2002]:

\[
K_p = T \omega_n^2
\]
\[
K_d = 2 \zeta \omega_n T - 1
\]
\[
K_i = \frac{\omega_n}{10} K_p
\]

where \( \zeta \) is the desired relative damping ratio and \( \omega_n \) is the desired natural frequency of the closed-loop system.

The feedforward term is chosen as:

\[
\tau_{FF} = \frac{T}{K} T \dot{r} + \frac{1}{K} r_d \quad (187)
\]

The resulting error dynamics is:

\[
T \ddot{r} + (1 + K_d) \dot{r} + K_p \ddot{\psi} + K_i \int_0^t \dot{\psi}(\tau) d\tau = 0 \quad (188)
\]

#### 10.3.2 New Autopilot Design for the Unified Model

The conventional autopilot can be extended to include the memory effect of the fluid. This has not been tested in a practical design as far as the author knows, but it is straightforward to derive a pole-placement algorithm that incorporates the frequency-dependent terms of the model.

Consider the unified model (180)–(183) in the form:

\[
\dot{\psi} = r \quad (189)
\]

\[
\dot{\psi} = r + [D + D_{mem}(s)]r + \alpha r^3 = \tau_{env} + \tau_N \quad (190)
\]

where

\[
M \triangleq I_z + \hat{M}_{A66}(\infty) \quad (191)
\]
\[
D \triangleq \hat{N}_{66}(\infty) \quad (192)
\]

and the transfer function matrix \( D_{mem}(s) \) (memory effects) is:

\[
D_{mem}(s) \triangleq c_r^T (sI - A_r)^{-1} b_r + d_r \quad (193)
\]

This is done with a gentle abuse of notation since the signal \( D_{mem}(s)r \) must be implemented by filtering \( r \) using \( D_{mem}(s). \)
A nonlinear PID-controller with feedforward:
\[
\tau_N = \tau_{FF} + \alpha r - K_p \dot{\psi} - K_d \dot{r} - K_i \int_0^t \psi(\tau) d\tau
\]
\[
\tau_{FF} = M \ddot{r} + [D + D_{mem}(s)] \dot{r}
\]
(194)
now gives the error dynamics:
\[
M \ddot{r} + [D_{mem}(s) + D + K_d] \dot{r} + K_p \dot{\psi} + K_i \int_0^t \psi(\tau) d\tau = \tau_{env}
\]
(195)
which represents a stable system for proper tuning of \( K_p, K_d, \) and \( K_i. \)

11 Dynamic Positioning and Maneuvering Systems

Already in the 1960s three decoupled PID-controllers were applied to control the horizontal motion of ships (surge, sway, and yaw) by means of thrusters and propellers. This was referred to as dynamic positioning (DP) systems. As for the autopilot systems, a challenging problem was to avoid that 1st-order wave-induced disturbances entered the feedback loop. Several techniques like notch and low-pass filtering and the use of dead-band techniques were tested for this purpose, but with different levels of success. In 1963 linear quadratic optimal controllers and the Kalman filter were published by Kalman and coauthors. This motivated the application of LQG-controllers in ship control since a state observer (Kalman filter) could be used to estimate the LF and WF motions. The LQG design technique was applied for this purpose by Balchen, Jenssen and Sælid (1976, 1980), and Grimble, Patton and Wise (1979, 1980). More lately, LQG control has been discussed by Sørensen et al. [1995]. Grimble and coauthors suggested to use \( H_\infty \) and \( \mu \)-methods [Katebi et al., 1997] for filtering and control in DP.

The control plant models for DP maneuvering systems will be classified according to the speed range in which the models are valid. Design of single model-based control system for DP and maneuvering at all speeds is currently an important field of research. This is the motivation for presenting the unified model of Section 5 since such a model can serve as basis for model-based control.

11.1 Speed Regimes

Strip theory programs can be applied on monohulls and catamarans at low as well as high speed. It is convenient to classify the models and speed regimes according to:

**Low Speed** \( U \in [0, U_{DP}] \) Dynamic positioning (station-keeping and low-speed maneuvering): Low-speed maneuvering is typically defined by the speed range in which a linear speed independent hydrodynamic model is valid. Experience suggests that:
\[
U_{DP} = 1.5 \text{ m/s} \approx 3 \text{ knots}
\]
(196)

(1) For DP applications in the horizontal plane (surge, sway, and yaw), the LF ship model can be approximated by [Fossen and Strand, 1999]:
\[
\dot{\psi}_{LF} = R(\psi) \nu_{LF}
\]
(197)
\[
M \ddot{\psi}_{LF} + D \dot{\psi}_{LF} + G \eta_{LF} = \tau + R^T(\psi) b
\]
(198)
\[
\eta = \eta_{LF} + \eta_{WF}
\]
(199)
where
\[
M = M_{RB} + J^T A(0) J^*, \quad \dot{M} = 0
\]
\[
D = J^T B(0) J^*
\]
\[
\tau = [\tau_1, \tau_2, \tau_0]^T
\]
(201)
\[
\mu = [u_{LF}, v_{LF}, \tau_{LF}]^T, \quad \eta_{LF} = [u_{LF}, e_{LF}, \psi_{LF}]^T, \quad \eta_{WF} = [u_{WF}, e_{WF}, \psi_{WF}]^T
\]
\[
R_{WF} \quad (\text{computed using RAOs or three linear shaping filters})
\]
\[
\eta = \eta_{LF} + \eta_{WF}
\]
(205)

(2) The unified DP model in a seaway can be written as, see Section 6.2:
\[
\dot{\eta} = R(\psi) \nu
\]
(206)
\[
M \dot{\nu} + D \nu + \mu + G \eta = \tau + R^T(\psi) b
\]
(207)
\[
\dot{b} = 0
\]
(208)
where
\[
M = M_{RB} + J^T A(\infty) J^*, \quad \dot{M} = 0
\]
\[
D = J^T B(\infty) J^*
\]
(210)

**Moderate Speed** \( U \in [U_{DP}, U_{max}] \) Maneuvering at moderate speeds: The maximum speed depends on the Froude number:
\[
F_h = \frac{U}{\sqrt{gL}}
\]
(211)
where \( L \) is the length of the ship. The traditional strip theory, developed by Salvesen et al. [1970], is valid up to \( F_n = 0.25\text{–}0.3 \). This suggests that:

\[
U_{\text{max}} = 0.3\sqrt{gL} \tag{212}
\]

Hence, for a 80 m long supply vessel \( U_{\text{max}} = 8.4 \) m/s.

1. The LF maneuvering model is described in Section 8.
2. The unified state-space model for this speed range is presented in Section 5.

**High Speed** \( U > U_{\text{max}} \) **High-speed maneuvering**: For high-speed craft lift theory must be taken into account. For Froude numbers \( F_n \geq 0.4 \), the high-speed formulation developed by Faltinsen and Zhao [1991a, 1991b] can be applied. In the Froude number range of 0.3–0.4, a comparison between the two methods should be carried out.

### 12.1 Marine Systems Simulator (MSS)

The Marine Systems Simulator (MSS) [MSS, 2004] at the Norwegian University of Science and Technology can be used for time-domain simulation of ShipX (VERES) strip theory coefficients in Matlab/Simulink (see Section 7.2 and Appendix B).

In the MSS two Matlab m-files for postprocessing of the ShipX (VERES) data are provided. These are:

- `Veres2ABC.m`: Computes the model matrices, retardation function, state-space models etc.
- `Veres2force.m`: Creates a table of generalized diffraction/Froude-Krylov force coefficients.

The data flow is shown in Figure 13 where the S-175 container ship is used as case study.

Figure 13: Flow chart showing the numerical computations.

The data file `Forces_TF.dat` is used as input for the Simulink program `VeresFRC_DP.mdl` while the file `ABC.mat` must be manually loaded into work space. The numerical recipes used in the postprocessing of the data are described in Fossen and Smogeli [2004].

The frequency-dependent added mass and potential damping coefficients including viscous effects are shown in Figure 15. Time series of hydrodynamic excitation forces are shown in Figure 16. The retardation functions are given in Figure 14. The numerical results are computed for beam seas with the JONSWAP wave spectrum using significant wave height \( H_{1/3} = 5 \) m and peak frequency \( \omega_p = 0.56 \) rad/s. The wave spreading factor was set to 4.

### 12 Conclusions

A unified state-space model for ship maneuvering, station-keeping, and control in a seaway has been presented in a vectorial setting using state-space models. A transformation procedure for the STF strip theory coefficients has been developed by formulating the time-domain equations of motion in the body-fixed reference frame instead of the equilibrium or hydrodynamic reference frame.
Figure 14: The retardation functions $K_{ij}$ are computed from (224) using trapezoidal integrations and plotted as a function of time $t$. The corresponding state-space models (5th-order) are plotted on top.

By doing this ill-conditioned terms like $U/\omega_e^2$ and $U^2/\omega_e^4$, which are undefined for $\omega_e = 0$, are avoided when computing the retardation functions. This gives excellent numerical properties for $U \geq 0$. The developed procedure has been motivated by the results of Bishop and Price [1981] and Bailey et al. [1998].

The unified model can be used to simulate ships and rigs in a seaway for varying sea states and at different speeds (including zero speed). The model is valid up to Froude numbers 0.25–0.3 which are the upper limit for conventional strip theory programs like ShipX (VERES) and SEAWAY. The unified model can also be related to the zero-frequency maneuvering model and it is possible to include nonlinear maneuvering terms by unifying the theories of seakeeping and maneuvering.

**Acknowledgment**

This project is sponsored by the Centre for Ships and Ocean Structures, NTNU, through The Research Council of Norway.

The author is grateful to Øyvind N. Smogeli, Erlend Kristiansen, Dr. Tristan Perez, Professor Odd Faltinsen, and Professor Olav Egeland for valuable discussions and proof reading.
Figure 15: Frequency-dependent added mass $A_{ii}$ and damping $B_{ii}$ ($i = 1...6$) for the S-175 container ship. Circles indicates VERES data points while the solid line is due to interpolation. For the $B_{ii}$-data, the high-frequency approximation $\beta_{ii}/\omega^3$ is applied. In addition, a viscous ramp function is added to the $B_{ii}$-plots. For surge, added mass $A_{11}$ is chosen as 10% of the mass while $B_{11}$ simply is a viscous ramp. Added resistance data can further be used to improve damping in surge. For roll, the viscous effect to due bilge keels (and possible anti-roll tanks) is included in the $B_{44}$-plot.
Figure 16: Diffraction and Froude-Krylov forces and moments in 6 DOF versus time, simulated in Simulink using VERES data tables.

A Cummins Equation

The hydromechanical reaction forces and moments, due to time-varying ship motions, can be described using Cummins [1962] formulation. From potential theory he showed that a rigid-body with generalized inertia matrix \( M^{*}_{RB} \) satisfies:

\[
M^{*}_{RB} \ddot{\xi} = \delta \tau_{H} + \delta \tau \tag{213}
\]

where \( \delta \tau \) is the generalized external force vector and \( \delta \tau_{H} \) is the hydrodynamic generalized force vector:

\[
\delta \tau_{H} = -\bar{A}^{*} \dot{\xi} - \int_{-\infty}^{t} \bar{K}^{*}(t-\tau) \dot{\xi}(\tau) d\tau - \bar{C}^{*} \xi \tag{214}
\]

in which \( \bar{A}^{*} \) is the generalized hydrodynamic added mass matrix, \( \bar{C}^{*} \) is the spring stiffness matrix, and \( \bar{K}^{*}(t-\tau) \) is a matrix of retardation functions. In honor of his work the time-domain equation:

\[
[M^{*}_{RB} + \bar{A}^{*}] \dddot{\xi} + \int_{-\infty}^{t} \bar{K}^{*}(t-\tau) \dot{\xi}(\tau) d\tau + \bar{C}^{*} \xi = \delta \tau \tag{215}
\]

is referred to as Cummins Equation.

A.1 Relationship between the Time and Frequency Domain Equations

The coefficients \( \bar{A}^{*}, \bar{C}^{*}, \) and \( \bar{K}^{*} \) in Cummins equation can be determined by using the approach of Ogilvie [1964]. The classical frequency domain description used in computer programs based on potential theory starts with (98), i.e.:

\[
[M^{*}_{RB} + A^{*}(\omega)] \ddot{\xi} + B^{*}(\omega) \dot{\xi} + C^{*} \xi = \delta \tau \tag{216}
\]

where the frequency-dependent hydrodynamic coefficient matrices \( A^{*}(\omega) \) and \( B^{*}(\omega) \) are due to added mass and po-
potential damping and $\delta \tau$ is a vector of generalized excitation forces.

In Ogilvie [1964] it is assumed that the floating object carries out oscillations:

$$\xi = \cos(\omega t)I_{6 \times 6}$$  \hspace{1cm} (217)

Substituting this expression into Cummins equation (215) gives:

$$-\omega^2 [M_{RB}^* + \bar{A}^*] \cos(\omega t) + \omega \int_0^\infty \tilde{K}^*(\tau) \sin(\omega t - \omega \tau) d\tau + \bar{C}^* \cos(\omega t) = \delta \tau$$

where we have replaced $\tau$ by $t - \tau$ in the integral. This gives:

$$-\omega^2 \{ [M_{RB}^* + \bar{A}^*] - \frac{1}{\omega} \int_0^\infty \tilde{K}^*(\tau) \sin(\omega \tau) d\tau \} \cos(\omega t)$$

$$-\omega \left\{ \int_0^\infty \tilde{K}^*(\tau) \cos(\omega \tau) d\tau \right\} \sin(\omega t)$$

$$+ \bar{C}^* \cos(\omega t) = \delta \tau$$  \hspace{1cm} (218)

The classical model (216) gives:

$$-\omega^2 \{ [M_{RB}^* + \bar{A}^*(\omega)] \cos(\omega t)$$

$$-\omega \{ B^*(\omega) \sin(\omega t) d\tau \} \sin(\omega t)$$

$$+ C^* \cos(\omega t) = \delta \tau$$  \hspace{1cm} (219)

By comparing the terms in (218) and (219), it is seen that:

$$A^*(\omega) = \bar{A}^* - \frac{1}{\omega} \int_0^\infty \tilde{K}^*(\tau) \sin(\omega \tau) d\tau$$  \hspace{1cm} (220)

$$B^*(\omega) = \int_0^\infty \tilde{K}^*(\tau) \cos(\omega \tau) d\tau$$  \hspace{1cm} (221)

$$C^* = \bar{C}^*$$  \hspace{1cm} (222)

The first equation must be valid for all $\omega$. Hence, we choose to evaluate (220) at $\omega = \infty$ implying that:

$$\bar{A}^* = A^*(\infty)$$  \hspace{1cm} (223)

The second equation is rewritten using the inverse Fourier transform giving:

$$\tilde{K}^*(t) = \frac{2}{\pi} \int_0^\infty B^*(\omega) \cos(\omega t) d\omega$$  \hspace{1cm} (224)

This expression is recognized as a matrix of retardation functions. Then, the relationship between the time-domain equation (215) and frequency-domain equation (216) has been established through:

$$[M_{RB}^* + A^*(\infty)] \ddot{\xi}$$

$$+ \int_t^\infty \tilde{K}^*(t - \tau) \dot{\xi}(\tau) d\tau + C^* \xi = \delta \tau$$  \hspace{1cm} (225)

### A.2 Alternative Representation for Numerical Computations

From a numerical point of view it is better to integrate:

$$K^*(t) = \frac{2}{\pi} \int_0^\infty [B^*(\omega) - B^*(\infty)] \cos(\omega \tau) d\omega$$  \hspace{1cm} (226)

than to use (224), since $B^*(\omega) - B^*(\infty)$ is zero at $\omega = \infty$. Hence, we rewrite (225) as:

$$[M_{RB}^* + A^*(\infty)] \ddot{\xi} + \int_t^\infty K^*(t - \tau) \dot{\xi}(\tau) d\tau + C^* \xi = \delta \tau$$

This can be shown by writing (224) as:

$$\tilde{K}^*(t) = \frac{2}{\pi} \int_0^\infty [B^*(\omega) - B^*(\infty) + B^*(\infty)] \cos(\omega \tau) d\omega$$

$$= K^*(t) + \frac{2}{\pi} \int_0^\infty B^*(\infty) \cos(\omega \tau) d\omega$$  \hspace{1cm} (227)

Hence:

$$\int_{-\infty}^t \tilde{K}^*(t - \tau) \dot{\xi}(\tau) d\tau$$

$$= \int_{-\infty}^t K^*(t - \tau) \dot{\xi}(\tau) d\tau + B^*(\infty) \dot{\xi}$$  \hspace{1cm} (228)

since the inverse Fourier transform of the constant $B^*(\infty)$ is an impulse. Moreover:

$$B^*(\infty) \dot{\xi} = \int_{-\infty}^\infty \left( \frac{2}{\pi} \int_0^\infty B^*(\infty) \cos(\omega \tau) d\omega \right) \dot{\xi}(\tau) d\tau$$  \hspace{1cm} (229)

### B STF Strip Theory

The STF strip theory coefficients can be decoupled into [Salvesen et al., 1970]:

- Longitudinal modes (surge, heave, pitch)
- Lateral modes (sway, roll, yaw)

The longitudinal coefficients are given in Table 3 and the lateral coefficients in Table 4. The superscript 0 denotes speed independent terms.
Table 3: Longitudinal STF Strip Theory Coefficients [Fathi and Hoff, 2004]. The signs have been modified to comply with the b-frame axes definition of Section 4.1.
